Features

- **80C52 Compatible**
  - **8051 Instruction Compatible**
  - **Six 8-bit I/O Ports (64 pins or 68 Pins Versions)**
  - **Four 8-bit I/O Ports (44 Pins Version)**
  - **Three 16-bit Timer/Counters**
  - **256 bytes Scratch Pad RAM**
  - **10 Interrupt Sources With 4 Priority Levels**
- **ISP (In-System Programming) Using Standard V_{CC} Power Supply**
- **Integrated Power Monitor (POR/PFD) to Supervise Internal Power Supply**
- **Boot ROM Contains Low Level Flash Programming Routines and a Default Serial Loader**
- **High-speed Architecture**
  - **In Standard Mode:**
    40 MHz (Vcc 2.7V to 5.5V, Both Internal and External Code Execution)
    60 MHz (Vcc 4.5V to 5.5V and Internal Code Execution Only)
  - **In X2 Mode (6 Clocks/Machine Cycle)**
    20 MHz (Vcc 2.7V to 5.5V, Both Internal and External Code Execution)
    30 MHz (Vcc 4.5V to 5.5V and Internal Code Execution Only)
- **64K bytes On-chip Flash Program/Data Memory**
  - **Byte and Page (128 bytes) Erase and Write**
  - **100k Write Cycles**
- **On-chip 1792 bytes Expanded RAM (XRAM)**
  - **Software Selectable Size (0, 256, 512, 768, 1024, 1792 bytes)**
  - **768 bytes Selected at Reset for T89C51RD2 Compatibility**
- **On-chip 2048 bytes EEPROM block for Data Storage**
  - **100k Write Cycles**
- **Dual Data Pointer**
- **32 KHz Crystal Oscillator**
- **Variable Length MOVX for Slow RAM/Peripherals**
- **Improved X2 Mode with Independant Selection for CPU and Each Peripheral**
- **Keyboard Interrupt Interface on Port 1**
- **SPI Interface (Master/Slave Mode)**
- **8-bit Clock Prescaler**
- **Two Wire Interface 400K bit/s**
- **Programmable Counter Array with:**
  - **High Speed Output**
  - **Compare/Capture**
  - **Pulse Width Modulator**
  - **Watchdog Timer Capabilities**
- **Asynchronous Port Reset**
- **Full Duplex Enhanced UART with Dedicated Internal Baud Rate Generator**
- **Low EMI (inhibit ALE)**
- **Hardware Watchdog Timer (One-time Enabled with Reset-Out), Power-Off Flag**
- **Power Control Modes: Idle Mode, Power-down Mode**
- **Power Supply: 2.7V to 5.5V**
- **Temperature Ranges: Industrial (-40 to +85°C)**
- **Packages: PLCC44, VQFP44, PLCC68$^{(1)}$, VQFP64$^{(1)}$**

Note: 1. Contact Atmel Sales for availability.

Description

AT89C51ID2 is a high performance CMOS Flash version of the 80C51 CMOS single chip 8-bit microcontroller. It contains a 64 Kbytes Flash memory block for program and for data.

8-bit Flash Microcontroller

AT89C51ID2

The 64 Kbytes Flash memory can be programmed either in parallel mode or in serial mode with the ISP capability or with software. The programming voltage is internally generated from the standard V_{CC} pin.

The AT89C51ID2 retains all features of the Atmel 80C52 with 256 bytes of internal RAM, a 10-source 4-level interrupt controller and three timer/counters.

In addition, the AT89C51ID2 has a Programmable Counter Array, an XRAM of 1792 bytes, a Hardware Watchdog Timer, SPI and Keyboard, a more versatile serial channel that facilitates multiprocessor communication (EUART) and a speed improvement mechanism (X2 mode).

The fully static design of the AT89C51ID2 allows to reduce system power consumption by bringing the clock frequency down to any value, even DC, without loss of data.

The AT89C51ID2 has 2 software-selectable modes of reduced activity and 8-bit clock prescaler for further reduction in power consumption. In the Idle mode the CPU is frozen while the peripherals and the interrupt system are still operating. In the power-down mode the RAM is saved and all other functions are inoperative.

The added features of the AT89C51ID2 make it more powerful for applications that need pulse width modulation, high speed I/O and counting capabilities such as alarms, motor control, corded phones, smart card readers.
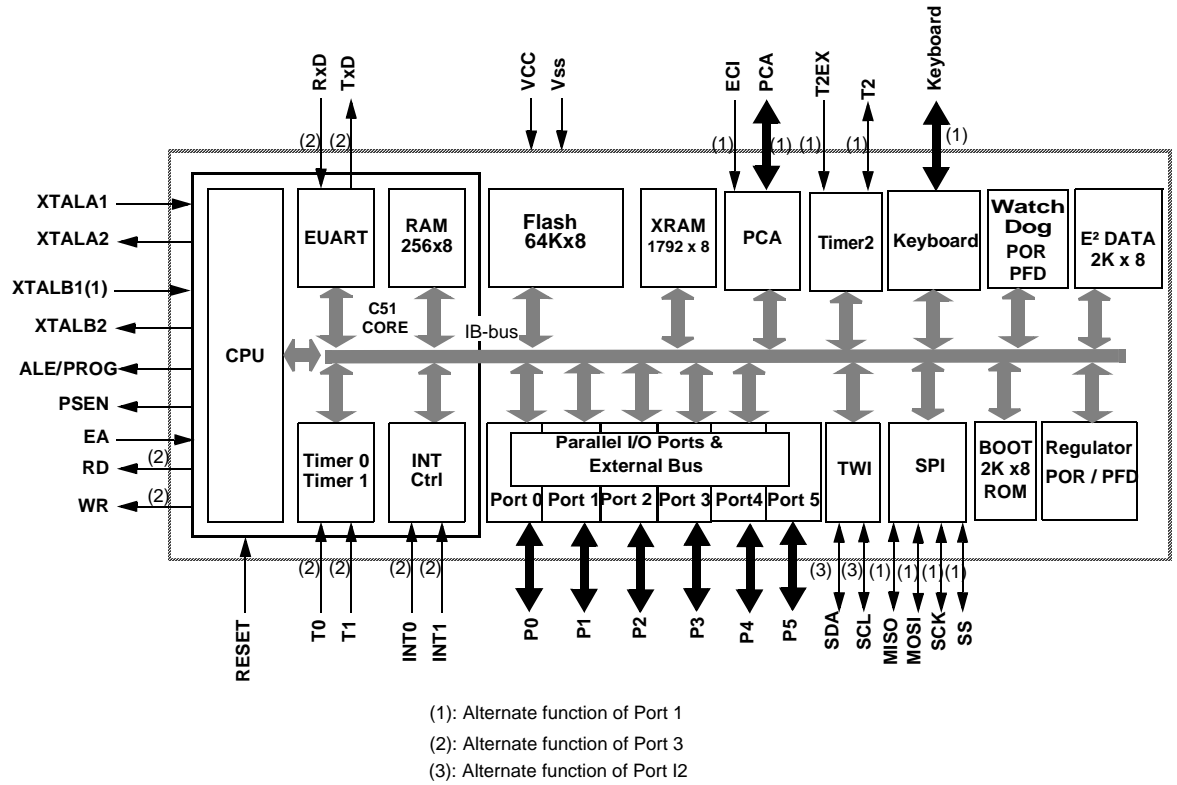

Table 1. Memory Size and I/O pins

AT89C51ID2	Flash (bytes)	XRAM (bytes)	TOTAL RAM (bytes)	I/O
PLCC44/VQFP44	64K	1792	2048	34
PLCC68/VQFP64 [1]	64K	1792	2048	50

SFR Mapping

The Special Function Registers (SFRs) of the AT89C51ID2 fall into the following categories:

- C51 core registers: ACC, B, DPH, DPL, PSW, SP
- I/O port registers: P0, P1, P2, P3, PI2
- Timer registers: T2CON, T2MOD, TCON, TH0, TH1, TH2, TMOD, TL0, TL1, TL2, RCAP2L, RCAP2H
- Serial I/O port registers: SADDR, SADEN, SBUF, SCON
- PCA (Programmable Counter Array) registers: CCON, CCAPMx, CL, CH, CCAPxH, CCAPxL (x: 0 to 4)
- Power and clock control registers: PCON
- Hardware Watchdog Timer registers: WDTRST, WDTPRG
- Interrupt system registers: IE0, IPL0, IPH0, IE1, IPL1, IPH1
- Keyboard Interface registers: KBE, KBF, KBLS
- SPI registers: SPCON, SPSTR, SPDAT
- 2-wire Interface registers: SSCON, SSCS, SSDAT, SSADR
- BRG (Baud Rate Generator) registers: BRL, BDRCON
- Flash register: FCON
- Clock Prescaler register: CKRL
- 32 kHz Sub Clock Oscillator registers: CKSEL, OSSCON
- Others: AUXR, AUXR1, CKCON0, CKCON1

Table 14. Pin Description

Mnemonic	Pin Number				Type	Name and Function
	PLCC44	VQFP44	PLCC68	VQFP64		
V_{SS}	22	16	51	40	I	**Ground:** 0V reference
V_{CC}	44	38	17	8	I	**Power Supply:** This is the power supply voltage for normal, idle and power-down operation
P0.0 - P0.7	43 - 36	37 - 30	15, 14, 12, 11, 9,6, 5, 3	6, 5, 3, 2, 64, 61,60,59	I/O	**Port 0**: Port 0 is an open-drain, bidirectional I/O port. Port 0 pins that have 1s written to them float and can be used as high impedance inputs. Port 0 must be polarized to V_{CC} or V_{SS} in order to prevent any parasitic current consumption. Port 0 is also the multiplexed low-order address and data bus during access to external program and data memory. In this application, it uses strong internal pull-up when emitting 1s. Port 0 also inputs the code bytes during EPROM programming. External pull-ups are required during program verification during which P0 outputs the code bytes.
P1.0 - P1.7	2 - 9	40 - 44 1 - 3	19, 21, 22, 23, 25, 27, 28, 29	10, 12, 13, 14, 16, 18, 19, 20	I/O	**Port 1:** Port 1 is an 8-bit bidirectional I/O port with internal pull-ups. Port 1 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, Port 1 pins that are externally pulled low will source current because of the internal pull-ups. Port 1 also receives the low-order address byte during memory programming and verification. Alternate functions for AT89C51ID2 Port 1 include:
	2	40	19	10	I/O	**P1.0**: Input/Output
					I/O	**T2 (P1.0):** Timer/Counter 2 external count input/Clockout
					I	**XTALB1 (P1.0):** Sub Clock input to the inverting oscillator amplifier
	3	41	21	12	I/O	**P1.1**: Input/Output
					I	**T2EX:** Timer/Counter 2 Reload/Capture/Direction Control
					I	$\overline{\text{SS}}$**:** SPI Slave Select
	4	42	22	13	I/O	**P1.2:** Input/Output
					I	**ECI:** External Clock for the PCA
	5	43	23	14	I/O	**P1.3:** Input/Output
					I/O	**CEX0:** Capture/Compare External I/O for PCA module 0
	6	44	25	16	I/O	**P1.4:** Input/Output
					I/O	**CEX1:** Capture/Compare External I/O for PCA module 1
	7	1	27	18	I/O	**P1.5:** Input/Output
					I/O	**CEX2:** Capture/Compare External I/O for PCA module 2
					I/O	**MISO:** SPI Master Input Slave Output line
						When SPI is in master mode, MISO receives data from the slave peripheral. When SPI is in slave mode, MISO outputs data to the master controller.
	8	2	28	19	I/O	**P1.6:** Input/Output
					I/O	**CEX3:** Capture/Compare External I/O for PCA module 3
					I/O	**SCK:** SPI Serial Clock
	9	3	29	20	I/O	**P1.7:** Input/Output:

Port 5 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, Port 4 pins that are externally pulled low will source current because of the internal pull-ups.
P5.0 - P5.7	-	-	60, 62, 63, 7, 8, 10, 13, 16	49, 51, 52, 62, 63, 1, 4, 7	I/O	**Port 5:** Port 5 is an 8-bit bidirectional I/O port with internal pull-ups. Port 3 pins that have 1s written to them are pulled high by the internal pull-ups and can be used as inputs. As inputs, Port 5 pins that are externally pulled low will source current because of the internal pull-ups.

Table 14. Pin Description (Continued)

Mnemonic	Pin Number				Type	Name and Function
	PLCC44	VQFP44	PLCC68	VQFP64		
PI2.0 - PI2.1	34, 12	28, 6	1, 36	57, 26		**Port I2:** Port I2 is an open drain. It can be used as inputs (must be polarized to Vcc with external resistor to prevent any parasitic current consumption).
	34	28	1	57	I/O	**SCL (PI2.0): 2-wire Serial Clock** SCL output the serial clock to slave peripherals SCL input the serial clock from master
	12	6	36	26	I/O	**SDA (PI2.1): 2-wire Serial Data** SDA is the bidirectional 2-wire data line
RST	10	4	30	21	I	**Reset:** A high on this pin for two machine cycles while the oscillator is running, resets the device. An internal diffused resistor to V_{SS} permits a power-on reset using only an external capacitor to V_{CC}. This pin is an output when the hardware watchdog forces a system reset.
ALE/$\overline{PROG}$	33	27	68	56	O (I)	**Address Latch Enable/Program Pulse:** Output pulse for latching the low byte of the address during an access to external memory. In normal operation, ALE is emitted at a constant rate of 1/6 (1/3 in X2 mode) the oscillator frequency, and can be used for external timing or clocking. Note that one ALE pulse is skipped during each access to external data memory. This pin is also the program pulse input ($\overline{PROG}$) during Flash programming. ALE can be disabled by setting SFR's AUXR.0 bit. With this bit set, ALE will be inactive during internal fetches.
PSEN	32	26	67	55	O	**Program Strobe ENable:** The read strobe to external program memory. When executing code from the external program memory, $\overline{PSEN}$ is activated twice each machine cycle, except that two $\overline{PSEN}$ activations are skipped during each access to external data memory. $\overline{PSEN}$ is not activated during fetches from internal program memory.
EA	35	29	2	58	I	**External Access Enable:** $\overline{EA}$ must be externally held low to enable the device to fetch code from external program memory locations 0000H to FFFFH. If security level 1 is programmed, $\overline{EA}$ will be internally latched on Reset.

Oscillators

Overview

Two oscillators are available for CPU:
- OSCA used for high frequency: Up to 40 MHz
- OSCB used for low frequency: 32.768 kHz

Several operating modes are available and programmable by software:
- to switch OSCA to OSCB and vice-versa
- to stop OSCA or OSCB to reduce consumption

In order to optimize the power consumption and the execution time needed for a specific task, an internal prescaler feature has been implemented between the selected oscillator and the CPU.

5	-	**Reserved** The value read from this bit is indeterminate. Do not set this bit.
4	POF	**Power-Off Flag** Cleared to recognize next reset type. Set by hardware when VCC rises from 0 to its nominal voltage. Can also be set by software.
3	GF1	**General purpose Flag** Cleared by software for general purpose usage. Set by software for general purpose usage.
2	GF0	**General purpose Flag** Cleared by software for general purpose usage. Set by software for general purpose usage.
1	PD	**Power-Down mode bit** Cleared by hardware when reset occurs. Set to enter power-down mode.
0	IDL	**Idle mode bit** Cleared by hardware when interrupt or reset occurs. Set to enter idle mode.

Reset Value = 00X1 0000b
Not bit addressable

Functional Block Diagram

Figure 2. Functional Oscillator Block Diagram
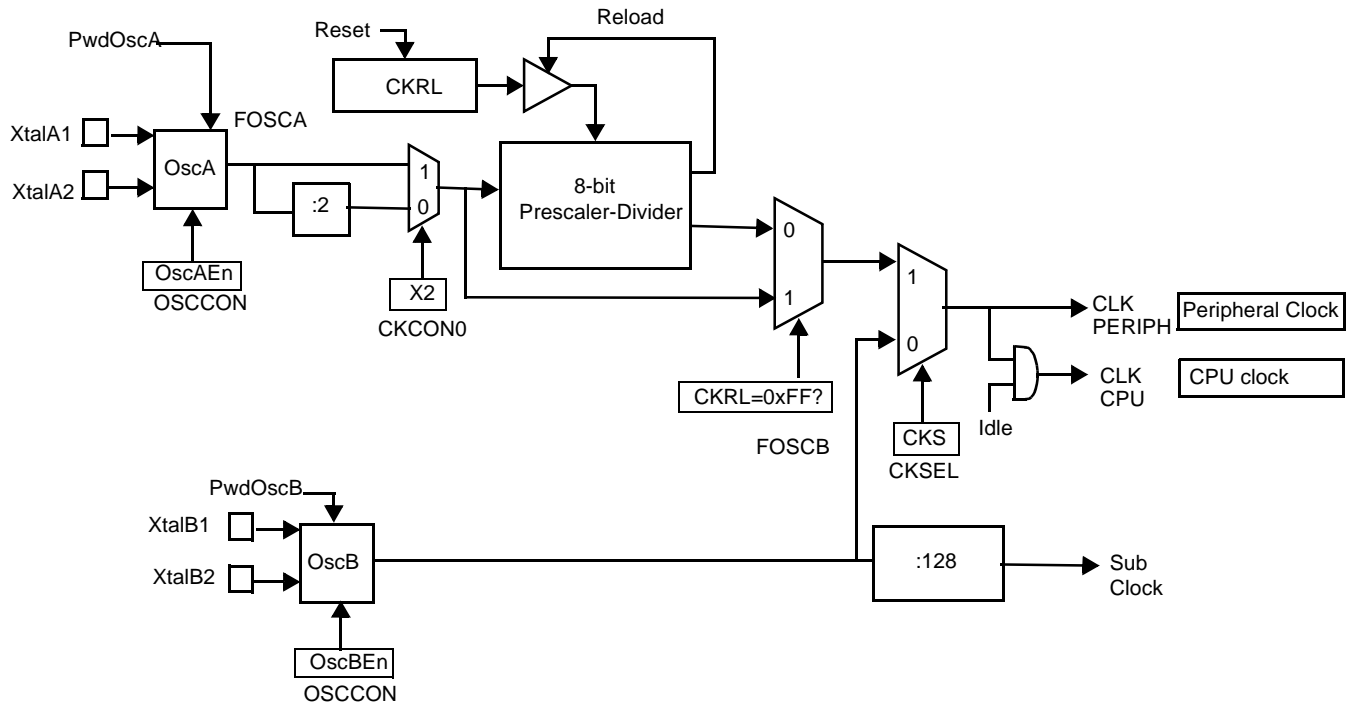

Operating Modes

Reset

A hardware RESET puts the Clock generator in the following state:

The selected oscillator depends on OSC bit in Hardware Security Byte (HSB).

HSB.OSC = 1 (Oscillator A selected)
- OscAEn = 1 & OscBEn = 0: OscA is running, OscB is stopped.
- CKS = 1: OscA is selected for CPU.

HSB.OSC = 0 (Oscillator B selected)
- OscAEn = 0 & OscBEn = 1: OscB is running, OscA is stopped.
- CKS = 0: OscB is selected for CPU.

Functional Modes

Normal Modes
- CPU and Peripherals clock depend on the software selection using CKCON0, CKCON1 and CKRL registers
- CKS bit in CKSEL register selects either OscA or OscB
- CKRL register determines the frequency of the OscA clock.

- It is always possible to switch dynamically by software from OscA to OscB, and vice versa by changing CKS bit.

Idle Modes

- IDLE modes are achieved by using any instruction that writes into PCON.0 bit (IDL)
- IDLE modes A and B depend on previous software sequence, prior to writing into PCON.0 bit:
- IDLE MODE A: OscA is running (OscAEn = 1) and selected (CKS = 1)
- IDLE MODE B: OscB is running (OscBEn = 1) and selected (CKS = 0)
- The unused oscillator OscA or OscB can be stopped by software by clearing OscAEn or OscBEn respectively.
- IDLE mode can be canceled either by Reset, or by activation of any enabled interruption
- In both cases, PCON.0 bit (IDL) is cleared by hardware
- Exit from IDLE modes will leave Oscillators control bits (OscEnA, OscEnB, CKS) unchanged.

Power Down Modes

- POWER DOWN modes are achieved by using any instruction that writes into PCON.1 bit (PD)
- POWER DOWN modes A and B depend on previous software sequence, prior to writing into PCON.1 bit:
- Both OscA and OscB will be stopped.
- POWER DOWN mode can be cancelled either by a hardware Reset, an external interruption, or the keyboard interrupt.
- By Reset signal: The CPU will restart according to OSC bit in Hardware Security Bit (HSB) register.
- By INT0 or INT1 interruption, if enabled: (standard behavioral), request on Pads must be driven low enough to ensure correct restart of the oscillator which was selected when entering in Power down.
- By keyboard Interrupt if enabled: a hardware clear of the PCON.1 flag ensure the restart of the oscillator which was selected when entering in Power down.

Table 19. Overview

PCON.1	PCON.0	OscBEn	OscAEn	CKS	Selected Mode	Comment
0	0	0	1	1	NORMAL MODE A, OscB stopped	Default mode after power-up or Warm Reset
0	0	1	1	1	NORMAL MODE A, OscB running	Default mode after power-up or Warm Reset + OscB running
0	0	1	0	0	NORMAL MODE B, OscA stopped	OscB running and selected
0	0	1	1	0	NORMAL MODE B, OscA running	OscB running and selected + OscA running
X	X	0	0	X	INVALID	OscA & OscB cannot be stopped at the same time
X	X	X	0	1	INVALID	OscA must not be stopped, as used for CPU and peripherals
X	X	0	X	0	INVALID	OscB must not be stopped as used for CPU and peripherals

Table 19. Overview (Continued)

PCON.1	PCON.0	OscBEn	OscAEn	CKS	Selected Mode	Comment
0	1	X	1	1	IDLE MODE A	The CPU is off, OscA supplies the peripherals, OscB can be disabled (OscBEn = 0)
0	1	1	X	0	IDLE MODE B	The CPU is off, OscB supplies the peripherals, OscA can be disabled (OscAEn = 0)
1	X	X	1	X	POWER DOWN MODE	The CPU and peripherals are off, OscA and OscB are stopped

Design Considerations

Oscillators Control

- PwdOscA and PwdOscB signals are generated in the Clock generator and used to control the hard blocks of oscillators A and B.
- PwdOscA ='1' stops OscA
- PwdOscB ='1' stops OscB
- The following tables summarize the Operating modes:

PCON.1	OscAEn	PwdOscA	Comments
0	1	0	OscA running
1	X	1	OscA stopped by Power-down mode
0	0	1	OscA stopped by clearing OscAEn

PCON.1	OscBEn	PwdOscB	Comments
0	1	0	OscB running
1	X	1	OscB stopped by Power-down mode
0	0	1	OscB stopped by clearing OscBEn

Prescaler Divider

- A hardware RESET puts the prescaler divider in the following state:
  - CKRL = FFh: $F_{CLK\ CPU} = F_{CLK\ PERIPH} = F_{OSCA}/2$ (Standard C51 feature)
- CKS signal selects OSCA or OSCB: $F_{CLK\ OUT} = F_{OSCA}$ or F_{OSCB}
- Any value between FFh down to 00h can be written by software into CKRL register in order to divide frequency of the selected oscillator:
  - CKRL = 00h: minimum frequency
    $F_{CLK\ CPU} = F_{CLK\ PERIPH} = F_{OSCA}/1020$ (Standard Mode)
    $F_{CLK\ CPU} = F_{CLK\ PERIPH} = F_{OSCA}/510$ (X2 Mode)
  - CKRL = FFh: maximum frequency
    $F_{CLK\ CPU} = F_{CLK\ PERIPH} = F_{OSCA}/2$ (Standard Mode)
    $F_{CLK\ CPU} = F_{CLK\ PERIPH} = F_{OSCA}$ (X2 Mode)

– $F_{CLK\ CPU}$ and $F_{CLK\ PERIPH}$, for CKRL<>0xFF
In X2 Mode:

$$F_{CPU} = F_{CLKPERIPH} = \frac{F_{OSCA}}{2 \times (255 - CKRL)}$$

In X1 Mode:

$$F_{CPU} = F_{CLKPERIPH} = \frac{F_{OSCA}}{4 \times (255 - CKRL)}$$

Timer 0: Clock Inputs

Figure 3. Timer 0: Clock Inputs
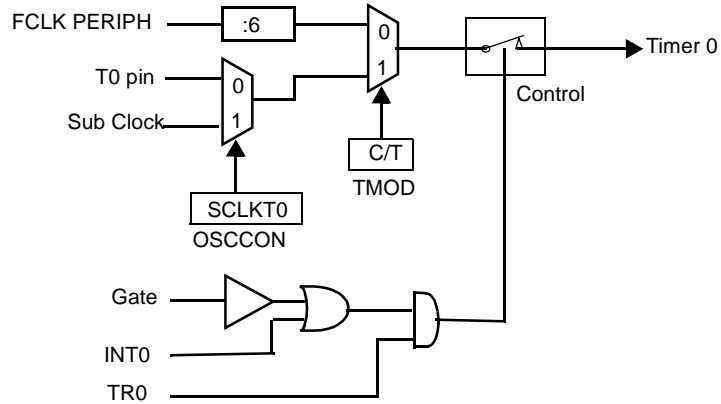

Note: The SCLKT0 bit in OSCCON register allows to select Timer 0 Subsidiary clock.

SCLKT0 = 0: Timer 0 uses the standard T0 pin as clock input (Standard mode)

SCLKT0 = 1: Timer 0 uses the special Sub Clock as clock input, this feature can be use as periodic interrupt for time clock.

Enhanced Features   In comparison to the original 80C52, the AT89C51ID2 implements some new features, which are:

- X2 option
- Dual Data Pointer
- Extended RAM
- Programmable Counter Array (PCA)
- Hardware Watchdog
- SPI interface
- 4-level interrupt priority system
- power-off flag
- ONCE mode
- ALE disabling
- Enhanced features on the UART and the timer 2

X2 Feature   The AT89C51ID2 core needs only 6 clock periods per machine cycle. This feature called 'X2' provides the following advantages:

- Divide frequency crystals by 2 (cheaper crystals) while keeping same CPU power.
- Save power consumption while keeping same CPU power (oscillator power saving).
- Save power consumption by dividing dynamically the operating frequency by 2 in operating and idle modes.
- Increase CPU power by 2 while keeping same crystal frequency.

In order to keep the original C51 compatibility, a divider by 2 is inserted between the XTAL1 signal and the main clock input of the core (phase generator). This divider may be disabled by software.

Description   The clock for the whole circuit and peripherals is first divided by two before being used by the CPU core and the peripherals.

This allows any cyclic ratio to be accepted on XTAL1 input. In X2 mode, as this divider is bypassed, the signals on XTAL1 must have a cyclic ratio between 40 to 60%.

Figure 4 shows the clock generation block diagram. X2 bit is validated on the rising edge of the XTAL1÷2 to avoid glitches when switching from X2 to STD mode. Figure 5 shows the switching mode waveforms.

Figure 4. Clock Generation Diagram
Figure 5. Mode Switching Waveforms
The X2 bit in the CKCON0 register (see Table 20) allows a switch from 12 clock periods per instruction to 6 clock periods and vice versa. At reset, the speed is set according to X2 bit of Hardware Security Byte (HSB). By default, Standard mode is active. Setting the X2 bit activates the X2 feature (X2 mode).

The T0X2, T1X2, T2X2, UartX2, PcaX2, and WdX2 bits in the CKCON0 register (See Table 20.) and SPIX2 bit in the CKCON1 register (see Table 21) allows a switch from standard peripheral speed (12 clock periods per peripheral clock cycle) to fast peripheral speed (6 clock periods per peripheral clock cycle). These bits are active only in X2 mode.

Table 20. CKCON0 Register

CKCON0 - Clock Control Register (8Fh)

7	6	5	4	3	2	1	0
TWIX2	WDX2	PCAX2	SIX2	T2X2	T1X2	T0X2	X2

Bit Number	Bit Mnemonic	Description
7	TWIX2	**2-wire clock** (This control bit is validated when the CPU clock X2 is set; when X2 is low, this bit has no effect) Cleared to select 6 clock periods per peripheral clock cycle. Set to select 12 clock periods per peripheral clock cycle.
6	WDX2	**Watchdog Clock** (This control bit is validated when the CPU clock X2 is set; when X2 is low, this bit has no effect). Cleared to select 6 clock periods per peripheral clock cycle. Set to select 12 clock periods per peripheral clock cycle.
5	PCAX2	**Programmable Counter Array Clock** (This control bit is validated when the CPU clock X2 is set; when X2 is low, this bit has no effect). Cleared to select 6 clock periods per peripheral clock cycle. Set to select 12 clock periods per peripheral clock cycle.
4	SIX2	**Enhanced UART Clock (Mode 0 and 2)** (This control bit is validated when the CPU clock X2 is set; when X2 is low, this bit has no effect). Cleared to select 6 clock periods per peripheral clock cycle. Set to select 12 clock periods per peripheral clock cycle.
3	T2X2	**Timer2 Clock** (This control bit is validated when the CPU clock X2 is set; when X2 is low, this bit has no effect). Cleared to select 6 clock periods per peripheral clock cycle. Set to select 12 clock periods per peripheral clock cycle.
2	T1X2	**Timer1 Clock** (This control bit is validated when the CPU clock X2 is set; when X2 is low, this bit has no effect). Cleared to select 6 clock periods per peripheral clock cycle. Set to select 12 clock periods per peripheral clock cycle.
1	T0X2	**Timer0 Clock** (This control bit is validated when the CPU clock X2 is set; when X2 is low, this bit has no effect). Cleared to select 6 clock periods per peripheral clock cycle. Set to select 12 clock periods per peripheral clock cycle.
0	X2	**CPU Clock** Cleared to select 12 clock periods per machine cycle (STD mode) for CPU and all the peripherals. Set to select 6clock periods per machine cycle (X2 mode) and to enable the individual peripherals'X2' bits. Programmed by hardware after Power-up regarding Hardware Security Byte (HSB), Default setting, X2 is cleared.

Reset Value = 0000 000'HSB. X2'b (See "Hardware Security Byte")
Not bit addressable

Reset Value = XXXX XXX0b
Not bit addressable

Dual Data Pointer Register DPTR

The additional data pointer can be used to speed up code execution and reduce code size.

The dual DPTR structure is a way by which the chip will specify the address of an external data memory location. There are two 16-bit DPTR registers that address the external memory, and a single bit called DPS = AUXR1.0 (see Table 22) that allows the program code to switch between them (Refer to Figure 6).

Figure 6. Use of Dual Pointer

External Data Memory

AUXR1(A2H)

DPH(83H) DPL(82H)
Table 22. AUXR1 register

AUXR1- Auxiliary Register 1(0A2h)

7	6	5	4	3	2	1	0
-	-	ENBOOT	-	GF3	0	-	DPS

Bit Number	Bit Mnemonic	Description
7	-	**Reserved** The value read from this bit is indeterminate. Do not set this bit.
6	-	**Reserved** The value read from this bit is indeterminate. Do not set this bit.
5	ENBOOT	**Enable Boot Flash** Cleared to disable boot ROM. Set to map the boot ROM between F800h - 0FFFFh.
4	-	**Reserved** The value read from this bit is indeterminate. Do not set this bit.
3	GF3	**This bit is a general purpose user flag. ***
2	0	**Always cleared.**
1	-	**Reserved** The value read from this bit is indeterminate. Do not set this bit.
0	DPS	**Data Pointer Selection** Cleared to select DPTR0. Set to select DPTR1.

Reset Value: XXXX XX0X0b

Not bit addressable

Note: *Bit 2 stuck at 0; this allows to use INC AUXR1 to toggle DPS without changing GF3.

ASSEMBLY LANGUAGE

```
; Block move using dual data pointers
; Modifies DPTR0, DPTR1, A and PSW
; note:  DPS exits opposite of entry state
; unless an extra INC AUXR1 is added
;
00A2    AUXR1 EQU 0A2H
;
0000 909000MOV DPTR,#SOURCE ; address of SOURCE
0003 05A2 INC AUXR1 ; switch data pointers
0005 90A000 MOV DPTR,#DEST ; address of DEST
0008    LOOP:
0008 05A2 INC AUXR1 ; switch data pointers
000A E0 MOVX A,@DPTR ; get a byte from SOURCE
000B A3 INC DPTR ; increment SOURCE address
000C 05A2 INC AUXR1 ; switch data pointers
000E F0 MOVX @DPTR,A ; write the byte to DEST
000F A3 INC DPTR ; increment DEST address
0010 70F6JNZ LOOP ; check for 0 terminator
0012 05A2 INC AUXR1 ; (optional) restore DPS
```

INC is a short (2 bytes) and fast (12 clocks) way to manipulate the DPS bit in the AUXR1 SFR. However, note that the INC instruction does not directly force the DPS bit to a particular state, but simply toggles it. In simple routines, such as the block move example, only the fact that DPS is toggled in the proper sequence matters, not its actual value. In other words, the block move routine works the same whether DPS is '0' or '1' on entry. Observe that without the last instruction (INC AUXR1), the routine will exit with DPS in the opposite state.

Expanded RAM (XRAM)

The AT89C51ID2 provides additional Bytes of random access memory (RAM) space for increased data parameter handling and high level language usage.

AT89C51ID2 devices have expanded RAM in external data space configurable up to 1792bytes (see Table 23.).

The AT89C51ID2 has internal data memory that is mapped into four separate segments.

The four segments are:

1. The Lower 128 bytes of RAM (addresses 00h to 7Fh) are directly and indirectly addressable.

2. The Upper 128 bytes of RAM (addresses 80h to FFh) are indirectly addressable only.

3. The Special Function Registers, SFRs, (addresses 80h to FFh) are directly addressable only.

4. The expanded RAM bytes are indirectly accessed by MOVX instructions, and with the EXTRAM bit cleared in the AUXR register (see Table 23).

The lower 128 bytes can be accessed by either direct or indirect addressing. The Upper 128 bytes can be accessed by indirect addressing only. The Upper 128 bytes occupy the same address space as the SFR. That means they have the same address, but are physically separate from SFR space.

Figure 7. Internal and External Data Memory Address
When an instruction accesses an internal location above address 7Fh, the CPU knows whether the access is to the upper 128 bytes of data RAM or to SFR space by the addressing mode used in the instruction.

- Instructions that use direct addressing access SFR space. For example: MOV 0A0H, # data, accesses the SFR at location 0A0h (which is P2).

- Instructions that use indirect addressing access the Upper 128 bytes of data RAM. For example: MOV @R0, # data where R0 contains 0A0h, accesses the data byte at address 0A0h, rather than P2 (whose address is 0A0h).

- The XRAM bytes can be accessed by indirect addressing, with EXTRAM bit cleared and MOVX instructions. This part of memory which is physically located on-chip, logically occupies the first bytes of external data memory. The bits XRS0 and XRS1 are used to hide a part of the available XRAM as explained in Table 23. This can be

useful if external peripherals are mapped at addresses already used by the internal XRAM.

- With <u>EXTRAM = 0,</u> the XRAM is indirectly addressed, using the MOVX instruction in combination with any of the registers R0, R1 of the selected bank or DPTR. An access to XRAM will not affect ports P0, P2, P3.6 (WR) and P3.7 (RD). For example, with EXTRAM = 0, MOVX @R0, # data where R0 contains 0A0H, accesses the XRAM at address 0A0H rather than external memory. An access to external data memory locations higher than the accessible size of the XRAM will be performed with the MOVX DPTR instructions in the same way as in the standard 80C51, with P0 and P2 as data/address busses, and P3.6 and P3.7 as write and read timing signals. Accesses to XRAM above 0FFH can only be done by the use of DPTR.

- With <u>EXTRAM = 1</u>, MOVX @Ri and MOVX @DPTR will be similar to the standard 80C51.MOVX @ Ri will provide an eight-bit address multiplexed with data on Port0 and any output port pins can be used to output higher order address bits. This is to provide the external paging capability. MOVX @DPTR will generate a sixteen-bit address. Port2 outputs the high-order eight address bits (the contents of DPH) while Port0 multiplexes the low-order eight address bits (DPL) with data. MOVX @ Ri and MOVX @DPTR will generate either read or write signals on P3.6 (WR) and P3.7 (RD).

The stack pointer (SP) may be located anywhere in the 256 bytes RAM (lower and upper RAM) internal data memory. The stack may not be located in the XRAM.

The M0 bit allows to stretch the XRAM timings; if M0 is set, the read and write pulses are extended from 6 to 30 clock periods. This is useful to access external slow peripherals.

Reset

Introduction

The reset sources are : Power Management, Hardware Watchdog, PCA Watchdog and Reset input.

Figure 8. Reset schematic
Reset Input

The Reset input can be used to force a reset pulse longer than the internal reset controlled by the Power Monitor. RST input has a pull-down resistor allowing power-on reset by simply connecting an external capacitor to V_{CC} as shown in Figure 9. Resistor value and input characteristics are discussed in the Section "DC Characteristics" of the AT89C51ID2 datasheet.

Figure 9. Reset Circuitry and Power-On Reset

a. RST input circuitry

b. Power-on Reset
Reset Output

As detailed in Section "Hardware Watchdog Timer", page 108, the WDT generates a 96-clock period pulse on the RST pin. In order to properly propagate this pulse to the rest of the application in case of external capacitor or power-supply supervisor circuit, a 1 kΩ resistor must be added as shown Figure 10.

Figure 10. Recommended Reset Output Schematic
Power Monitor

The POR/PFD function monitors the internal power-supply of the CPU core memories and the peripherals, and if needed, suspends their activity when the internal power supply falls below a safety threshold. This is achieved by applying an internal reset to them.

By generating the Reset the Power Monitor insures a correct start up when AT89C51ID2 is powered up.

Description

In order to startup and maintain the microcontroller in correct operating mode, V_{CC} has to be stabilized in the V_{CC} operating range and the oscillator has to be stabilized with a nominal amplitude compatible with logic level VIH/VIL.

These parameters are controlled during the three phases: power-up, normal operation and power going down. See Figure 11.

Figure 11. Power Monitor Block Diagram
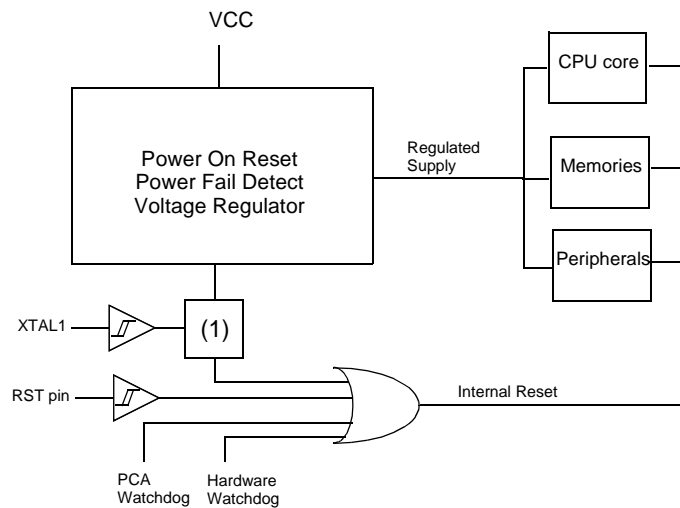

Note: 1. Once XTAL1 High and low levels reach above and below VIH/VIL. a 1024 clock period delay will extend the reset coming from the Power Fail Detect. If the power falls below the Power Fail Detect threshold level, the Reset will be applied immediately.

The Voltage regulator generates a regulated internal supply for the CPU core the memories and the peripherals. Spikes on the external Vcc are smoothed by the voltage regulator.

The Power fail detect monitor the supply generated by the voltage regulator and generate a reset if this supply falls below a safety threshold as illustrated in the Figure 12 below.

Figure 12. Power Fail Detect
When the power is applied, the Power Monitor immediately asserts a reset. Once the internal supply after the voltage regulator reach a safety level, the power monitor then looks at the XTAL clock input. The internal reset will remain asserted until the Xtal1 levels are above and below VIH and VIL. Further more. An internal counter will count 1024 clock periods before the reset is de-asserted.

If the internal power supply falls below a safety level, a reset is immediately asserted.

Timer 2

The Timer 2 in the AT89C51ID2 is the standard C52 Timer 2.

It is a 16-bit timer/counter: the count is maintained by two eight-bit timer registers, TH2 and TL2 are cascaded. It is controlled by T2CON (Table 24) and T2MOD (Table 25) registers. Timer 2 operation is similar to Timer 0 and Timer 1.C/$\overline{T2}$ selects F_{OSC}/12 (timer operation) or external pin T2 (counter operation) as the timer clock input. Setting TR2 allows TL2 to increment by the selected input.

Timer 2 has 3 operating modes: capture, autoreload and Baud Rate Generator. These modes are selected by the combination of RCLK, TCLK and CP/$\overline{RL2}$ (T2CON).

Refer to the Atmel 8-bit Microcontroller Hardware description for the description of Capture and Baud Rate Generator Modes.

Timer 2 includes the following enhancements:

- Auto-reload mode with up or down counter
- Programmable clock-output

Auto-Reload Mode

The auto-reload mode configures Timer 2 as a 16-bit timer or event counter with automatic reload. If DCEN bit in T2MOD is cleared, Timer 2 behaves as in 80C52 (refer to the Atmel C51 Microcontroller Hardware description). If DCEN bit is set, Timer 2 acts as an Up/down timer/counter as shown in Figure 13. In this mode the T2EX pin controls the direction of count.

When T2EX is high, Timer 2 counts up. Timer overflow occurs at FFFFh which sets the TF2 flag and generates an interrupt request. The overflow also causes the 16-bit value in RCAP2H and RCAP2L registers to be loaded into the timer registers TH2 and TL2.

When T2EX is low, Timer 2 counts down. Timer underflow occurs when the count in the timer registers TH2 and TL2 equals the value stored in RCAP2H and RCAP2L registers. The underflow sets TF2 flag and reloads FFFFh into the timer registers.

The EXF2 bit toggles when Timer 2 overflows or underflows according to the direction of the count. EXF2 does not generate any interrupt. This bit can be used to provide 17-bit resolution.

Figure 13. Auto-Reload Mode Up/Down Counter (DCEN = 1)
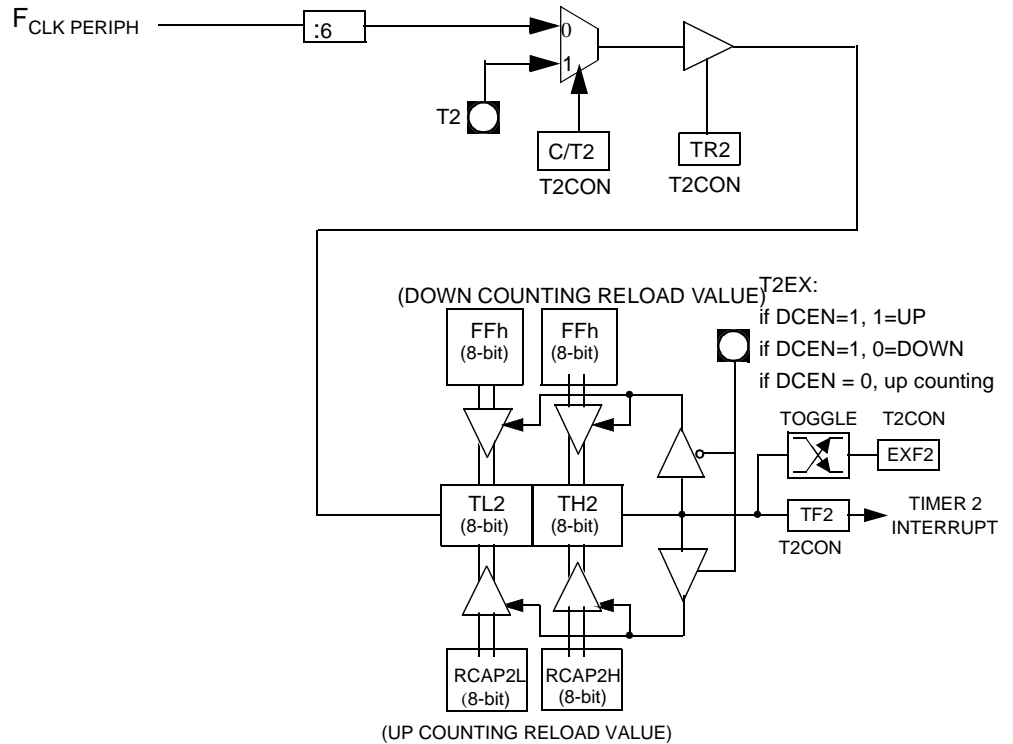

Programmable Clock-Output

In the clock-out mode, Timer 2 operates as a 50%-duty-cycle, programmable clock generator (See Figure 14). The input clock increments TL2 at frequency $F_{CLK\ PERIPH}/2$. The timer repeatedly counts to overflow from a loaded value. At overflow, the contents of RCAP2H and RCAP2L registers are loaded into TH2 and TL2. In this mode, Timer 2 overflows do not generate interrupts. The formula gives the clock-out frequency as a function of the system oscillator frequency and the value in the RCAP2H and RCAP2L registers:

$$Clock-Out Frequency = \frac{F_{CLKPERIPH}}{4 \times (65536 - RCAP2H/RCAP2L)}$$

For a 16 MHz system clock, Timer 2 has a programmable frequency range of 61 Hz ($F_{CLK\ PERIPH}/2^{16}$) to 4 MHz ($F_{CLK\ PERIPH}/4$). The generated clock signal is brought out to T2 pin (P1.0).

Timer 2 is programmed for the clock-out mode as follows:

- Set T2OE bit in T2MOD register.
- Clear C/$\overline{T2}$ bit in T2CON register.
- Determine the 16-bit reload value from the formula and enter it in RCAP2H/RCAP2L registers.
- Enter a 16-bit initial value in timer registers TH2/TL2. It can be the same as the reload value or a different one depending on the application.
- To start the timer, set TR2 run control bit in T2CON register.

It is possible to use Timer 2 as a baud rate generator and a clock generator simultaneously. For this configuration, the baud rates and clock frequencies are not independent since both functions use the values in the RCAP2H and RCAP2L registers.

Registers

Table 24. T2CON Register

T2CON - Timer 2 Control Register (C8h)

7	6	5	4	3	2	1	0
TF2	EXF2	RCLK	TCLK	EXEN2	TR2	C/T2#	CP/RL2#

Bit Number	Bit Mnemonic	Description
7	TF2	**Timer 2 overflow Flag** Must be cleared by software. Set by hardware on Timer 2 overflow, if RCLK = 0 and TCLK = 0.
6	EXF2	**Timer 2 External Flag** Set when a capture or a reload is caused by a negative transition on T2EX pin if EXEN2=1. When set, causes the CPU to vector to Timer 2 interrupt routine when Timer 2 interrupt is enabled. Must be cleared by software. EXF2 doesn't cause an interrupt in Up/down counter mode (DCEN = 1).
5	RCLK	**Receive Clock bit** Cleared to use timer 1 overflow as receive clock for serial port in mode 1 or 3. Set to use Timer 2 overflow as receive clock for serial port in mode 1 or 3.
4	TCLK	**Transmit Clock bit** Cleared to use timer 1 overflow as transmit clock for serial port in mode 1 or 3. Set to use Timer 2 overflow as transmit clock for serial port in mode 1 or 3.
3	EXEN2	**Timer 2 External Enable bit** Cleared to ignore events on T2EX pin for Timer 2 operation. Set to cause a capture or reload when a negative transition on T2EX pin is detected, if Timer 2 is not used to clock the serial port.
2	TR2	**Timer 2 Run control bit** Cleared to turn off Timer 2. Set to turn on Timer 2.
1	C/T2#	**Timer/Counter 2 select bit** Cleared for timer operation (input from internal clock system: $F_{CLK\ PERIPH}$). Set for counter operation (input from T2 input pin, falling edge trigger). Must be 0 for clock out mode.
0	CP/RL2#	**Timer 2 Capture/Reload bit** If RCLK=1 or TCLK=1, CP/RL2# is ignored and timer is forced to auto-reload on Timer 2 overflow. Cleared to auto-reload on Timer 2 overflows or negative transitions on T2EX pin if EXEN2=1. Set to capture on negative transitions on T2EX pin if EXEN2=1.

Programmable Counter Array PCA

The PCA provides more timing capabilities with less CPU intervention than the standard timer/counters. Its advantages include reduced software overhead and improved accuracy. The PCA consists of a dedicated timer/counter which serves as the time base for an array of five compare/capture modules. Its clock input can be programmed to count any one of the following signals:

- Peripheral clock frequency ($F_{CLK\ PERIPH}$) ÷ 6
- Peripheral clock frequency ($F_{CLK\ PERIPH}$) ÷ 2
- Timer 0 overflow
- External input on ECI (P1.2)

Each compare/capture modules can be programmed in any one of the following modes:

- Rising and/or falling edge capture
- Software timer
- High-speed output
- Pulse width modulator

Module 4 can also be programmed as a watchdog timer (See Section "PCA Watchdog Timer", page 52).

When the compare/capture modules are programmed in the capture mode, software timer, or high speed output mode, an interrupt can be generated when the module executes its function. All five modules plus the PCA timer overflow share one interrupt vector.

The PCA timer/counter and compare/capture modules share Port 1 for external I/O. These pins are listed below. If the port is not used for the PCA, it can still be used for standard I/O.

PCA component	External I/O Pin
16-bit Counter	P1.2 / ECI
16-bit Module 0	P1.3 / CEX0
16-bit Module 1	P1.4 / CEX1
16-bit Module 2	P1.5 / CEX2
16-bit Module 3	P1.6 / CEX3

The PCA timer is a common time base for all five modules (See Figure 15). The timer count source is determined from the CPS1 and CPS0 bits in the CMOD register (Table 26) and can be programmed to run at:

- 1/6 the peripheral clock frequency ($F_{CLK\ PERIPH}$)
- 1/2 the peripheral clock frequency ($F_{CLK\ PERIPH}$)
- The Timer 0 overflow
- The input on the ECI pin (P1.2)

Reset Value = 00XX X000b
Not bit addressable

The CMOD register includes three additional bits associated with the PCA (See Figure 15 and Table 26).

- The CIDL bit which allows the PCA to stop during idle mode.
- The WDTE bit which enables or disables the watchdog function on module 4.
- The ECF bit which when set causes an interrupt and the PCA overflow flag CF (in the CCON SFR) to be set when the PCA timer overflows.

The CCON register contains the run control bit for the PCA and the flags for the PCA timer (CF) and each module (Refer to Table 27).

- Bit CR (CCON.6) must be set by software to run the PCA. The PCA is shut off by clearing this bit.
- Bit CF: The CF bit (CCON.7) is set when the PCA counter overflows and an interrupt will be generated if the ECF bit in the CMOD register is set. The CF bit can only be cleared by software.

• Bits 0 through 4 are the flags for the modules (bit 0 for module 0, bit 1 for module 1, etc.) and are set by hardware when either a match or a capture occurs. These flags also can only be cleared by software.

Table 27. CCON Register

6	CR	**PCA Counter Run control bit** Must be cleared by software to turn the PCA counter off. Set by software to turn the PCA counter on.
5	-	**Reserved** The value read from this bit is indeterminate. Do not set this bit.
4	CCF4	**PCA Module 4 interrupt flag** Must be cleared by software. Set by hardware when a match or capture occurs.
3	CCF3	**PCA Module 3 interrupt flag** Must be cleared by software. Set by hardware when a match or capture occurs.
2	CCF2	**PCA Module 2 interrupt flag** Must be cleared by software. Set by hardware when a match or capture occurs.
1	CCF1	**PCA Module 1 interrupt flag** Must be cleared by software. Set by hardware when a match or capture occurs.
0	CCF0	**PCA Module 0 interrupt flag** Must be cleared by software. Set by hardware when a match or capture occurs.

Reset Value = 00X0 0000b
Not bit addressable

The watchdog timer function is implemented in module 4 (See Figure 18).

The PCA interrupt system is shown in Figure 16.

Figure 16. PCA Interrupt System
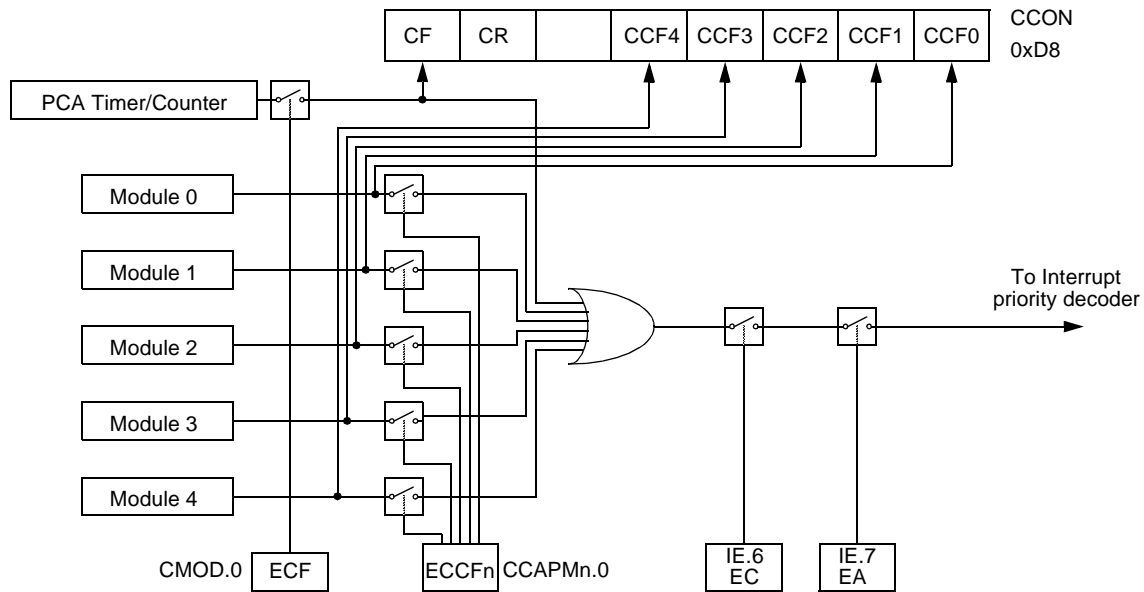

PCA Modules: each one of the five compare/capture modules has six possible functions. It can perform:

- 16-bit Capture, positive-edge triggered
- 16-bit Capture, negative-edge triggered
- 16-bit Capture, both positive and negative-edge triggered
- 16-bit Software Timer
- 16-bit High Speed Output
- 8-bit Pulse Width Modulator

In addition, module 4 can be used as a Watchdog Timer.

Each module in the PCA has a special function register associated with it. These registers are: CCAPM0 for module 0, CCAPM1 for module 1, etc. (See Table 28). The registers contain the bits that control the mode that each module will operate in.

- The ECCF bit (CCAPMn.0 where n=0, 1, 2, 3, or 4 depending on the module) enables the CCF flag in the CCON SFR to generate an interrupt when a match or compare occurs in the associated module.
- PWM (CCAPMn.1) enables the pulse width modulation mode.
- The TOG bit (CCAPMn.2) when set causes the CEX output associated with the module to toggle when there is a match between the PCA counter and the module's capture/compare register.
- The match bit MAT (CCAPMn.3) when set will cause the CCFn bit in the CCON register to be set when there is a match between the PCA counter and the module's capture/compare register.
- The next two bits CAPN (CCAPMn.4) and CAPP (CCAPMn.5) determine the edge that a capture input will be active on. The CAPN bit enables the negative edge, and the CAPP bit enables the positive edge. If both bits are set both edges will be enabled and a capture will occur for either transition.
- The last bit in the register ECOM (CCAPMn.6) when set enables the comparator function.

Table 28 shows the CCAPMn settings for the various PCA functions.

PCA Capture Mode

To use one of the PCA modules in the capture mode either one or both of the CCAPM bits CAPN and CAPP for that module must be set. The external CEX input for the module (on port 1) is sampled for a transition. When a valid transition occurs the PCA hardware loads the value of the PCA counter registers (CH and CL) into the module's capture registers (CCAPnL and CCAPnH). If the CCFn bit for the module in the CCON SFR and the ECCFn bit in the CCAPMn SFR are set then an interrupt will be generated (Refer to Figure 17).

Figure 17. PCA Capture Mode
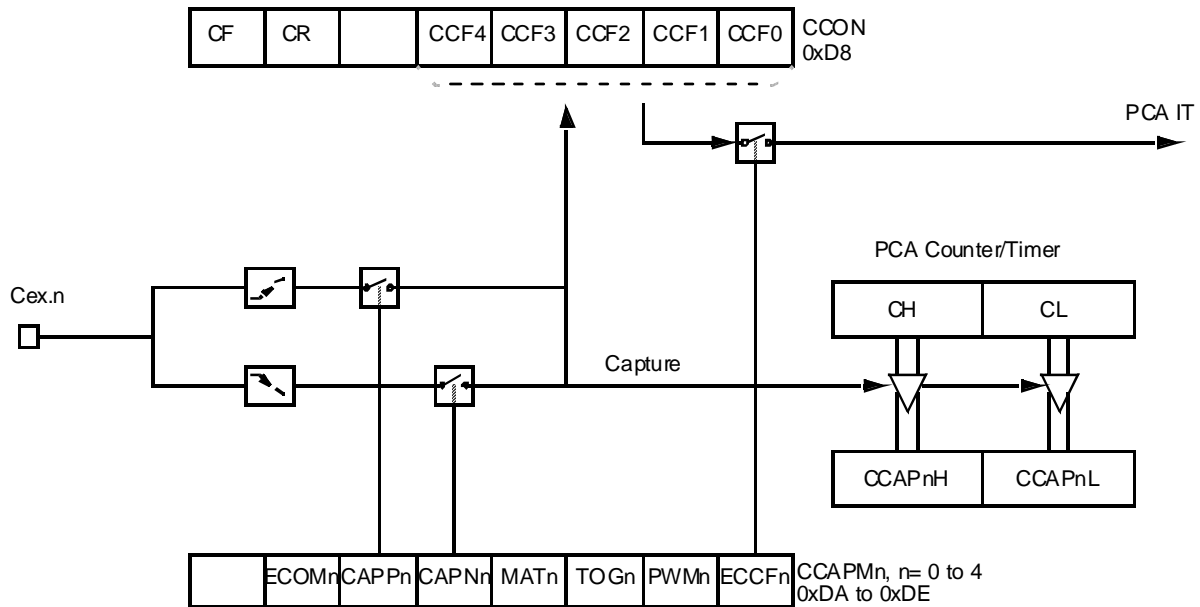

16-bit Software Timer/ Compare Mode

The PCA modules can be used as software timers by setting both the ECOM and MAT bits in the modules CCAPMn register. The PCA timer will be compared to the module's capture registers and when a match occurs an interrupt will occur if the CCFn (CCON SFR) and the ECCFn (CCAPMn SFR) bits for the module are both set (See Figure 18).

Figure 18. PCA Compare Mode and PCA Watchdog Timer
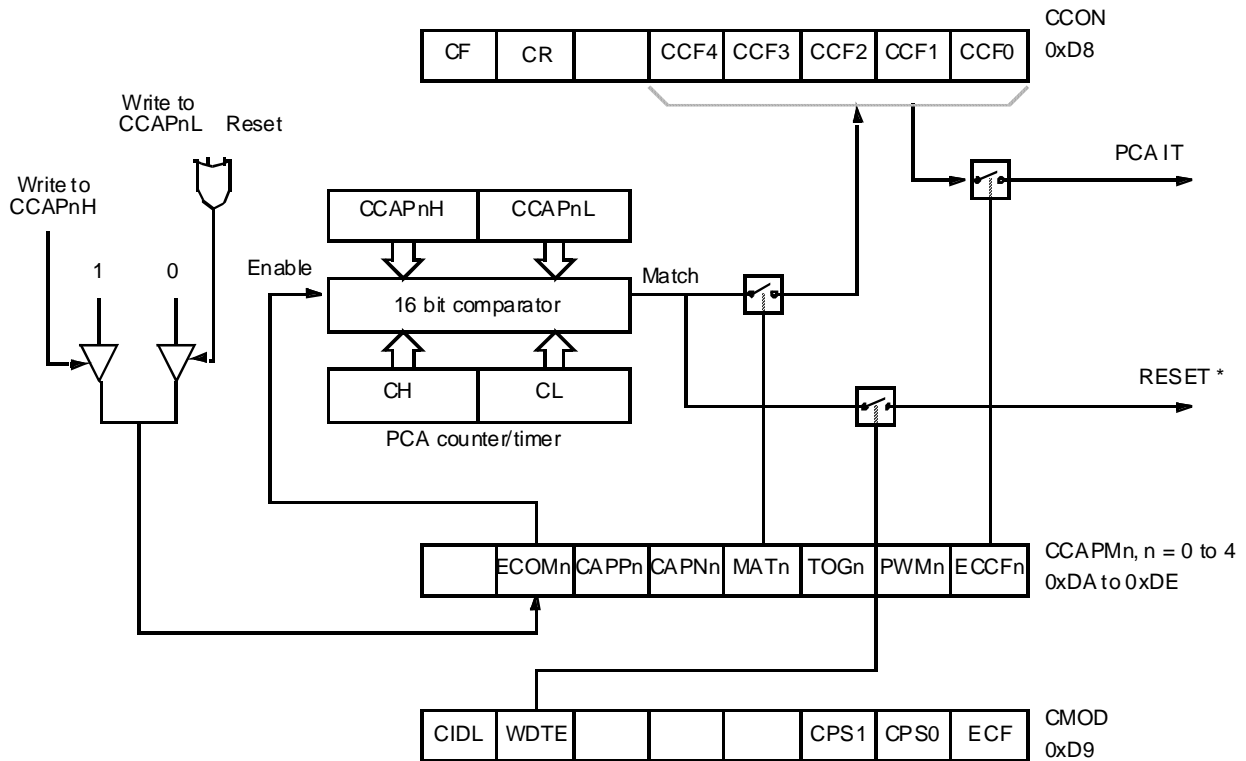

Before enabling ECOM bit, CCAPnL and CCAPnH should be set with a non zero value, otherwise an unwanted match could happen. Writing to CCAPnH will set the ECOM bit.

Once ECOM set, writing CCAPnL will clear ECOM so that an unwanted match doesn't occur while modifying the compare value. Writing to CCAPnH will set ECOM. For this reason, user software should write CCAPnL first, and then CCAPnH. Of course, the ECOM bit can still be controlled by accessing to CCAPMn register.

High Speed Output Mode   In this mode the CEX output (on port 1) associated with the PCA module will toggle each time a match occurs between the PCA counter and the module's capture registers. To activate this mode the TOG, MAT, and ECOM bits in the module's CCAPMn SFR must be set (See Figure 19).

A prior write must be done to CCAPnL and CCAPnH before writing the ECOMn bit.

Figure 19. PCA High Speed Output Mode
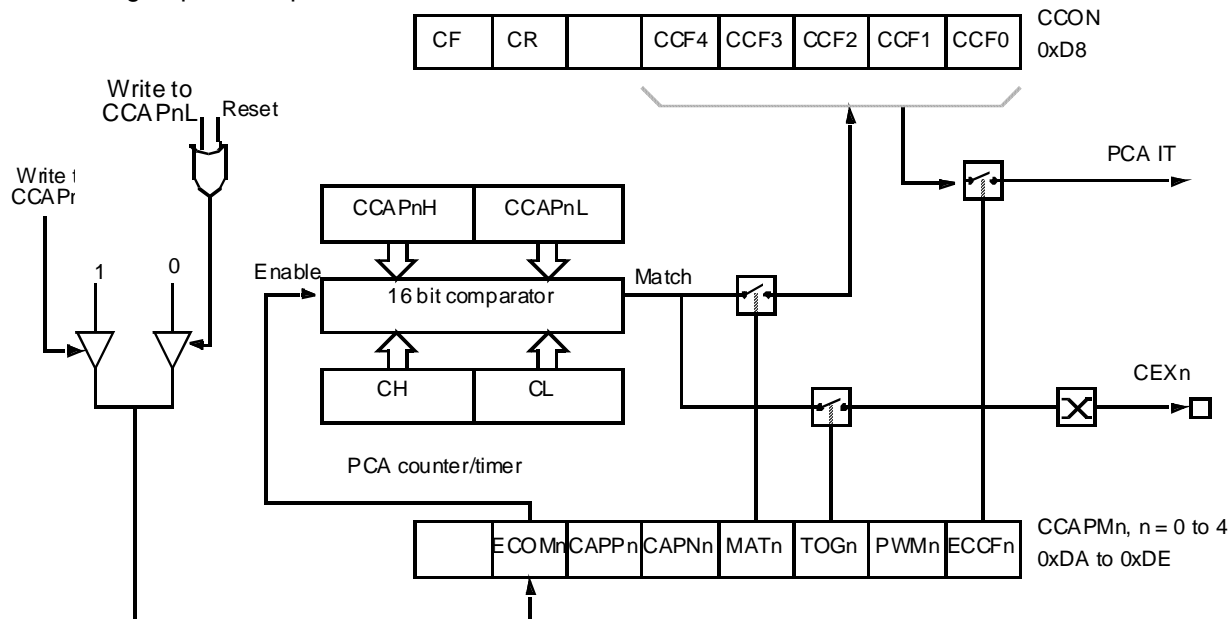

Before enabling ECOM bit, CCAPnL and CCAPnH should be set with a non zero value, otherwise an unwanted match could happen.

Once ECOM set, writing CCAPnL will clear ECOM so that an unwanted match doesn't occur while modifying the compare value. Writing to CCAPnH will set ECOM. For this reason, user software should write CCAPnL first, and then CCAPnH. Of course, the ECOM bit can still be controlled by accessing to CCAPMn register.

Pulse Width Modulator Mode

All of the PCA modules can be used as PWM outputs. Figure 20 shows the PWM function. The frequency of the output depends on the source for the PCA timer. All of the modules will have the same frequency of output because they all share the PCA timer. The duty cycle of each module is independently variable using the module's capture register CCAPLn. When the value of the PCA CL SFR is less than the value in the module's CCAPLn SFR the output will be low, when it is equal to or greater than the output will be high. When CL overflows from FF to 00, CCAPLn is reloaded with the value in CCAPHn. This allows updating the PWM without glitches. The PWM and ECOM bits in the module's CCAPMn register must be set to enable the PWM mode.

Figure 20. PCA PWM Mode

PCA Watchdog Timer

An on-board watchdog timer is available with the PCA to improve the reliability of the system without increasing chip count. Watchdog timers are useful for systems that are susceptible to noise, power glitches, or electrostatic discharge. Module 4 is the only PCA module that can be programmed as a watchdog. However, this module can still be used for other modes if the watchdog is not needed. Figure 18 shows a diagram of how the watchdog works. The user pre-loads a 16-bit value in the compare registers. Just like the other compare modes, this 16-bit value is compared to the PCA timer value. If a match is allowed to occur, an internal reset will be generated. This will not cause the RST pin to be driven high.

In order to hold off the reset, the user has three options:

1. periodically change the compare value so it will never match the PCA timer,

2. periodically change the PCA timer value so it will never match the compare values, or

3. disable the watchdog by clearing the WDTE bit before a match occurs and then re-enable it.

The first two options are more reliable because the watchdog timer is never disabled as in option #3. If the program counter ever goes astray, a match will eventually occur and cause an internal reset. The second option is also not recommended if other PCA modules are being used. Remember, the PCA timer is the time base for all modules; changing the time base for other modules would not be a good idea. Thus, in most applications the first solution is the best option.

This watchdog timer won't generate a reset out on the reset pin.

Serial I/O Port

The serial I/O port in the AT89C51ID2 is compatible with the serial I/O port in the 80C52. It provides both synchronous and asynchronous communication modes. It operates as a Universal Asynchronous Receiver and Transmitter (UART) in three full-duplex modes (Modes 1, 2 and 3). Asynchronous transmission and reception can occur simultaneously and at different baud rates

Serial I/O port includes the following enhancements:

* Framing error detection
* Automatic address recognition

Framing Error Detection

Framing bit error detection is provided for the three asynchronous modes (modes 1, 2 and 3). To enable the framing bit error detection feature, set SMOD0 bit in PCON register (See Figure 21).

Figure 21. Framing Error Block Diagram
When this feature is enabled, the receiver checks each incoming data frame for a valid stop bit. An invalid stop bit may result from noise on the serial lines or from simultaneous transmission by two CPUs. If a valid stop bit is not found, the Framing Error bit (FE) in SCON register (See Table 37.) bit is set.

Software may examine FE bit after each reception to check for data errors. Once set, only software or a reset can clear FE bit. Subsequently received frames with valid stop bits cannot clear FE bit. When FE feature is enabled, RI rises on stop bit instead of the last data bit (See Figure 22. and Figure 23.).

Figure 22. UART Timings in Mode 1
Figure 23. UART Timings in Modes 2 and 3
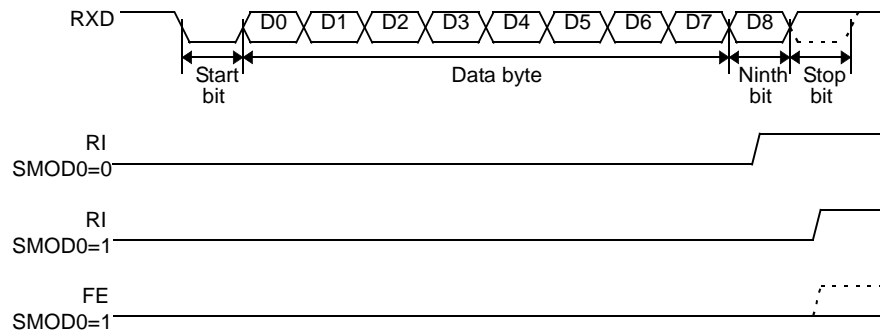

Automatic Address Recognition

The automatic address recognition feature is enabled when the multiprocessor communication feature is enabled (SM2 bit in SCON register is set).

Implemented in hardware, automatic address recognition enhances the multiprocessor communication feature by allowing the serial port to examine the address of each incoming command frame. Only when the serial port recognizes its own address, the receiver sets RI bit in SCON register to generate an interrupt. This ensures that the CPU is not interrupted by command frames addressed to other devices.

If desired, the user may enable the automatic address recognition feature in mode 1.In this configuration, the stop bit takes the place of the ninth data bit. Bit RI is set only when the received command frame address matches the device's address and is terminated by a valid stop bit.

To support automatic address recognition, a device is identified by a given address and a broadcast address.

Note: The multiprocessor communication and automatic address recognition features cannot be enabled in mode 0 (i. e. setting SM2 bit in SCON register in mode 0 has no effect).

Given Address

Each device has an individual address that is specified in SADDR register; the SADEN register is a mask byte that contains don't-care bits (defined by zeros) to form the device's given address. The don't-care bits provide the flexibility to address one or more slaves at a time. The following example illustrates how a given address is formed.

To address a device by its individual address, the SADEN mask byte must be 1111 1111b.

For example:

SADDR   0101 0110b
SADEN   1111 1100b

Given   0101 01XXb

The following is an example of how to use given addresses to address different slaves:

Slave A: SADDR   1111 0001b
           SADEN   1111 1010b

           Given   1111 0X0Xb

Slave B: SADDR   1111 0011b
           SADEN   1111 1001b

           Given   1111 0XX1b

Slave C: SADDR   1111 0010b
           SADEN   1111 1101b

           Given   1111 00X1b

The SADEN byte is selected so that each slave may be addressed separately.

For slave A, bit 0 (the LSB) is a don't-care bit; for slaves B and C, bit 0 is a 1.To communicate with slave A only, the master must send an address where bit 0 is clear (e. g. `1111 0000b`).

For slave A, bit 1 is a 1; for slaves B and C, bit 1 is a don't care bit. To communicate with slaves B and C, but not slave A, the master must send an address with bits 0 and 1 both set (e. g. `1111 0011b`).

To communicate with slaves A, B and C, the master must send an address with bit 0 set, bit 1 clear, and bit 2 clear (e. g. `1111 0001b`).

Broadcast Address

A broadcast address is formed from the logical OR of the SADDR and SADEN registers with zeros defined as don't-care bits, e. g. :

SADDR0101 0110b
SADEN1111 1100b

Broadcast =SADDR OR SADEN1111 111Xb

The use of don't-care bits provides flexibility in defining the broadcast address, however in most applications, a broadcast address is FFh. The following is an example of using broadcast addresses:

Slave A:SADDR1111 0001b
SADEN1111 1010b

Broadcast1111 1X11b,

Slave B:SADDR1111 0011b
SADEN1111 1001b

Broadcast1111 1X11B,

Slave C:SADDR=1111 0011b
SADEN1111 1101b

Broadcast1111 1111b

For slaves A and B, bit 2 is a don't care bit; for slave C, bit 2 is set. To communicate with all of the slaves, the master must send an address FFh. To communicate with slaves A and B, but not slave C, the master can send and address FBh.

Reset Addresses

On reset, the SADDR and SADEN registers are initialized to 00h, i. e. the given and broadcast addresses are `xxxx xxxxb` (all don't-care bits). This ensures that the serial port will reply to any address, and so, that it is backwards compatible with the 80C51 microcontrollers that do not support automatic address recognition.

Baud Rate Selection for UART for Mode 1 and 3

The Baud Rate Generator for transmit and receive clocks can be selected separately via the T2CON and BDRCON registers.

Figure 24. Baud Rate Selection
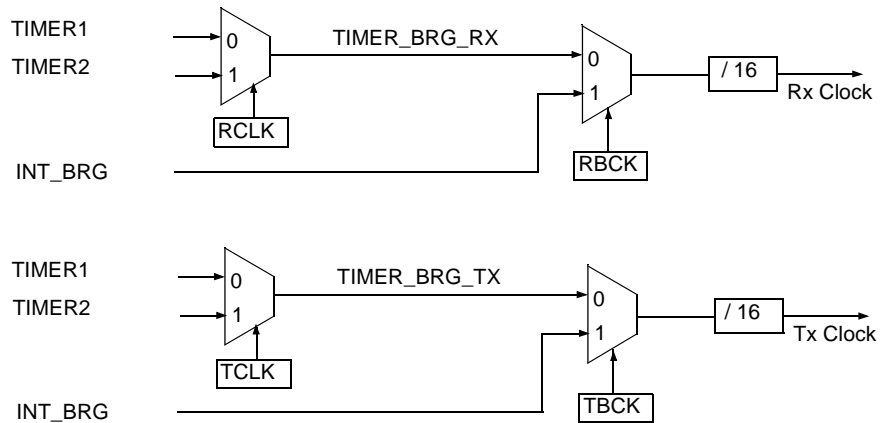

Table 36. Baud Rate Selection Table UART

TCLK (T2CON)	RCLK (T2CON)	TBCK (BDRCON)	RBCK (BDRCON)	Clock Source UART Tx	Clock Source UART Rx
0	0	0	0	Timer 1	Timer 1
1	0	0	0	Timer 2	Timer 1
0	1	0	0	Timer 1	Timer 2
1	1	0	0	Timer 2	Timer 2
X	0	1	0	INT_BRG	Timer 1
X	1	1	0	INT_BRG	Timer 2
0	X	0	1	Timer 1	INT_BRG
1	X	0	1	Timer 2	INT_BRG
X	X	1	1	INT_BRG	INT_BRG

Internal Baud Rate Generator (BRG)

When the internal Baud Rate Generator is used, the Baud Rates are determined by the BRG overflow depending on the BRL reload value, the value of SPD bit (Speed Mode) in BDRCON register and the value of the SMOD1 bit in PCON register.

Figure 25. Internal Baud Rate
- The baud rate for UART is token by formula:

$$Baud\_Rate = \frac{2^{SMOD1} \cdot F_{PER}}{6^{(1-SPD)} \cdot 32 \cdot (256 - BRL)}$$

$$BRL = 256 - \frac{2^{SMOD1} \cdot F_{PER}}{6^{(1-SPD)} \cdot 32 \cdot Baud\_Rate}$$

Table 37. SCON Register

SCON - Serial Control Register (98h)

7	6	5	4	3	2	1	0
FE/SM0	SM1	SM2	REN	TB8	RB8	TI	RI

Bit Number	Bit Mnemonic	Description
7	FE	**Framing Error bit (SMOD0=1)** Clear to reset the error state, not cleared by a valid stop bit. Set by hardware when an invalid stop bit is detected. SMOD0 must be set to enable access to the FE bit.
	SM0	**Serial port Mode bit 0** Refer to SM1 for serial port mode selection. SMOD0 must be cleared to enable access to the SM0 bit.
6	SM1	**Serial port Mode bit 1** SM0SM1ModeDescriptionBaud Rate 0 0 0Shift Register$F_{CPU\ PERIPH}$/6 0 1 18-bit UARTVariable 1 0 29-bit UART$F_{CPU\ PERIPH}$/32 or /16 1 1 39-bit UARTVariable
5	SM2	**Serial port Mode 2 bit / Multiprocessor Communication Enable bit** Clear to disable multiprocessor communication feature. Set to enable multiprocessor communication feature in mode 2 and 3, and eventually mode 1.This bit should be cleared in mode 0.
4	REN	**Reception Enable bit** Clear to disable serial reception. Set to enable serial reception.
3	TB8	**Transmitter Bit 8 / Ninth bit to transmit in modes 2 and 3** Clear to transmit a logic 0 in the 9th bit. Set to transmit a logic 1 in the 9th bit.
2	RB8	**Receiver Bit 8 / Ninth bit received in modes 2 and 3** Cleared by hardware if 9th bit received is a logic 0. Set by hardware if 9th bit received is a logic 1. In mode 1, if SM2 = 0, RB8 is the received stop bit. In mode 0 RB8 is not used.
1	TI	**Transmit Interrupt flag** Clear to acknowledge interrupt. Set by hardware at the end of the 8th bit time in mode 0 or at the beginning of the stop bit in the other modes.
0	RI	**Receive Interrupt flag** Clear to acknowledge interrupt. Set by hardware at the end of the 8th bit time in mode 0, see Figure 22. and Figure 23. in the other modes.

Reset Value = 0000 0000b
Bit addressable

Table 38. Example of Computed Value When X2=1, SMOD1=1, SPD=1

Baud Rates	F_{OSC} = 16. 384 MHz		F_{OSC} = 24MHz

Bit Number	Bit Mnemonic	Description
7	TF2	**Timer 2 overflow Flag** Must be cleared by software. Set by hardware on timer 2 overflow, if RCLK = 0 and TCLK = 0.
6	EXF2	**Timer 2 External Flag** Set when a capture or a reload is caused by a negative transition on T2EX pin if EXEN2=1. When set, causes the CPU to vector to timer 2 interrupt routine when timer 2 interrupt is enabled. Must be cleared by software. EXF2 doesn't cause an interrupt in Up/down counter mode (DCEN = 1)
5	RCLK	**Receive Clock bit for UART** Cleared to use timer 1 overflow as receive clock for serial port in mode 1 or 3. Set to use timer 2 overflow as receive clock for serial port in mode 1 or 3.
4	TCLK	**Transmit Clock bit for UART** Cleared to use timer 1 overflow as transmit clock for serial port in mode 1 or 3. Set to use timer 2 overflow as transmit clock for serial port in mode 1 or 3.
3	EXEN2	**Timer 2 External Enable bit** Cleared to ignore events on T2EX pin for timer 2 operation. Set to cause a capture or reload when a negative transition on T2EX pin is detected, if timer 2 is not used to clock the serial port.
2	TR2	**Timer 2 Run control bit** Cleared to turn off timer 2. Set to turn on timer 2.
1	C/T2#	**Timer/Counter 2 select bit** Cleared for timer operation (input from internal clock system: $F_{CLK\ PERIPH}$). Set for counter operation (input from T2 input pin, falling edge trigger). Must be 0 for clock out mode.
0	CP/RL2#	**Timer 2 Capture/Reload bit** If RCLK=1 or TCLK=1, CP/RL2# is ignored and timer is forced to auto-reload on timer 2 overflow. Cleared to auto-reload on timer 2 overflows or negative transitions on T2EX pin if EXEN2=1. Set to capture on negative transitions on T2EX pin if EXEN2=1.

4	BRR	**Baud Rate Run Control bit** Cleared to stop the internal Baud Rate Generator. Set to start the internal Baud Rate Generator.
3	TBCK	**Transmission Baud rate Generator Selection bit for UART** Cleared to select Timer 1 or Timer 2 for the Baud Rate Generator. Set to select internal Baud Rate Generator.
2	RBCK	**Reception Baud Rate Generator Selection bit for UART** Cleared to select Timer 1 or Timer 2 for the Baud Rate Generator. Set to select internal Baud Rate Generator.
1	SPD	**Baud Rate Speed Control bit for UART** Cleared to select the SLOW Baud Rate Generator. Set to select the FAST Baud Rate Generator.
0	SRC	**Baud Rate Source select bit in Mode 0 for UART** Cleared to select F_{OSC}/12 as the Baud Rate Generator ($F_{CLK PERIPH}$/6 in X2 mode). Set to select the internal Baud Rate Generator for UARTs in mode 0.

Reset Value = XXX0 0000b
Not bit addressablef

Interrupt System

The AT89C51ID2 has a total of 10 interrupt vectors: two external interrupts ($\overline{INT0}$ and $\overline{INT1}$), three timer interrupts (timers 0, 1 and 2), the serial port interrupt, SPI interrupt, Keyboard interrupt and the PCA global interrupt. These interrupts are shown in Figure 26.

Figure 26. Interrupt Control System
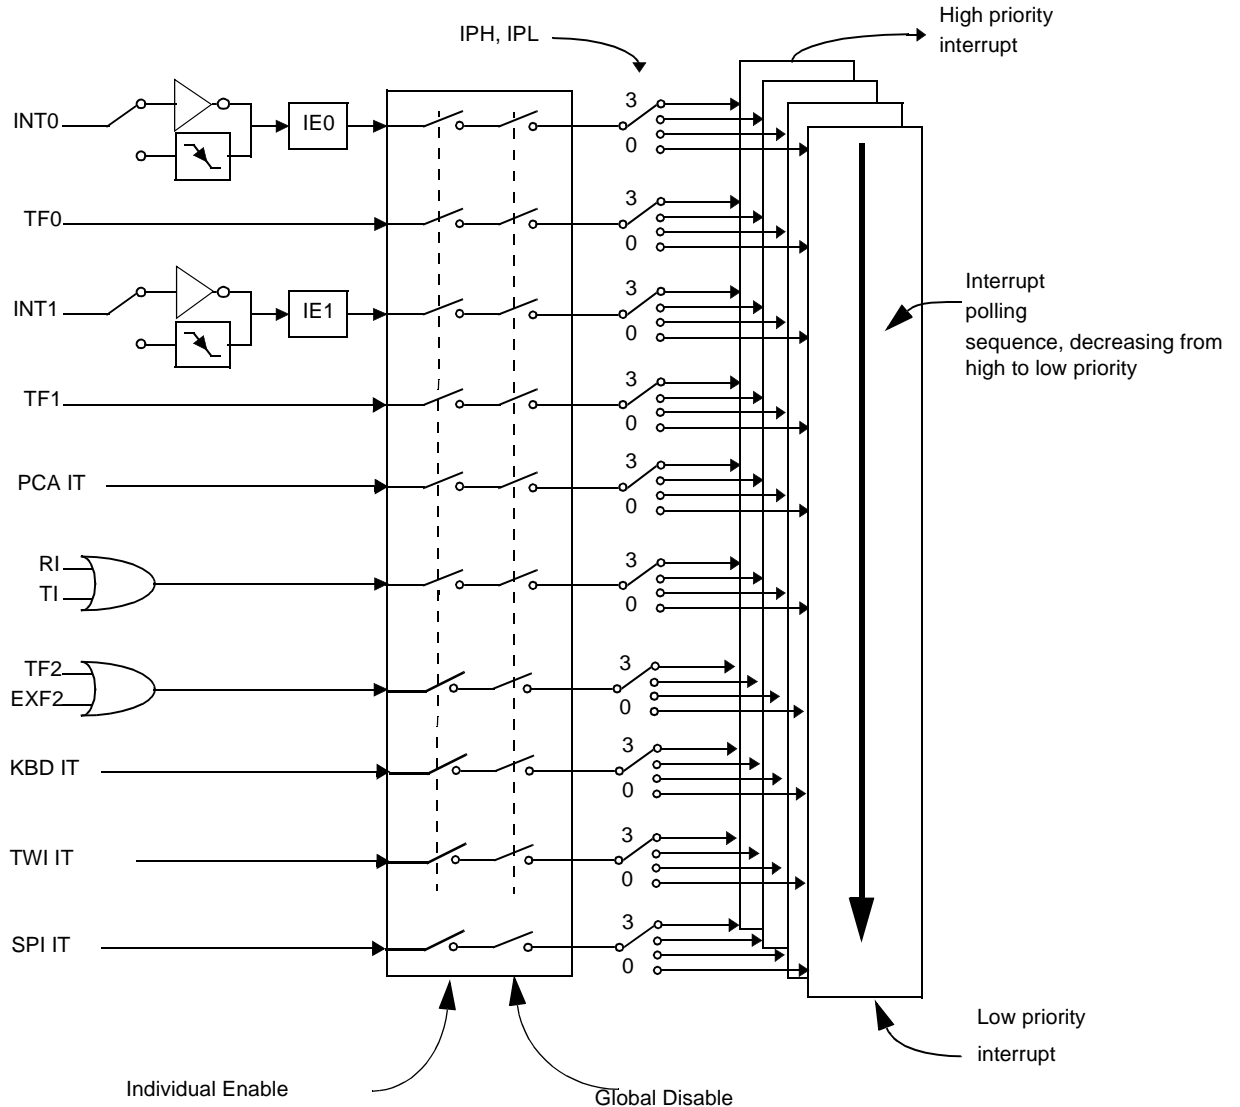

Each of the interrupt sources can be individually enabled or disabled by setting or clearing a bit in the Interrupt Enable register (Table 51 and Table 49). This register also contains a global disable bit, which must be cleared to disable all interrupts at once.

Each interrupt source can also be individually programmed to one out of four priority levels by setting or clearing a bit in the Interrupt Priority register (Table 52) and in the Interrupt Priority High register (Table 50 and Table 51) shows the bit values and priority levels associated with each combination.

Registers

The PCA interrupt vector is located at address 0033H, the SPI interrupt vector is located at address 0043H and Keyboard interrupt vector is located at address 004BH. All other vectors addresses are the same as standard C52 devices.

Table 47. Priority Level Bit Values

IPH. x	IPL. x	Interrupt Level Priority
0	0	0 (Lowest)
0	1	1
1	0	2
1	1	3 (Highest)

A low-priority interrupt can be interrupted by a high priority interrupt, but not by another low-priority interrupt. A high-priority interrupt can't be interrupted by any other interrupt source.

If two interrupt requests of different priority levels are received simultaneously, the request of higher priority level is serviced. If interrupt requests of the same priority level are received simultaneously, an internal polling sequence determines which request is serviced. Thus within each priority level there is a second priority structure determined by the polling sequence.

Power Management

Introduction

Two power reduction modes are implemented in the AT89C51ID2. The Idle mode and the Power-Down mode. These modes are detailed in the following sections. In addition to these power reduction modes, the clocks of the core and peripherals can be dynamically divided by 2 using the X2 mode detailed in Section "Enhanced Features", page 22.

Idle Mode

Idle mode is a power reduction mode that reduces the power consumption. In this mode, program execution halts. Idle mode freezes the clock to the CPU at known states while the peripherals continue to be clocked. The CPU status before entering Idle mode is preserved, i.e., the program counter and program status word register retain their data for the duration of Idle mode. The contents of the SFRs and RAM are also retained. The status of the Port pins during Idle mode is detailed in Table 56.

Entering Idle Mode

To enter Idle mode, set the IDL bit in PCON register (see Table 57). The AT89C51ID2 enters Idle mode upon execution of the instruction that sets IDL bit. The instruction that sets IDL bit is the last instruction executed.

Note: If IDL bit and PD bit are set simultaneously, the AT89C51ID2 enters Power-Down mode. Then it does not go in Idle mode when exiting Power-Down mode.

Exiting Idle Mode

There are two ways to exit Idle mode:

1. Generate an enabled interrupt.

   – Hardware clears IDL bit in PCON register which restores the clock to the CPU. Execution resumes with the interrupt service routine. Upon completion of the interrupt service routine, program execution resumes with the instruction immediately following the instruction that activated Idle mode. The general purpose flags (GF1 and GF0 in PCON register) may be used to indicate whether an interrupt occurred during normal operation or during Idle mode. When Idle mode is exited by an interrupt, the interrupt service routine may examine GF1 and GF0.

2. Generate a reset.

   – A logic high on the RST pin clears IDL bit in PCON register directly and asynchronously. This restores the clock to the CPU. Program execution momentarily resumes with the instruction immediately following the instruction that activated the Idle mode and may continue for a number of clock cycles before the internal reset algorithm takes control. Reset initializes the AT89C51ID2 and vectors the CPU to address C:0000h.

Note: During the time that execution resumes, the internal RAM cannot be accessed; however, it is possible for the Port pins to be accessed. To avoid unexpected outputs at the Port pins, the instruction immediately following the instruction that activated Idle mode should not write to a Port pin or to the external RAM.

Power-Down Mode

The Power-Down mode places the AT89C51ID2 in a very low power state. Power-Down mode stops the oscillator, freezes all clock at known states. The CPU status prior to entering Power-Down mode is preserved, i.e., the program counter, program status word register retain their data for the duration of Power-Down mode. In addition, the SFR

and RAM contents are preserved. The status of the Port pins during Power-Down mode is detailed in Table 56.

Note: VCC may be reduced to as low as V_{RET} during Power-Down mode to further reduce power dissipation. Take care, however, that VDD is not reduced until Power-Down mode is invoked.

Entering Power-Down Mode   To enter Power-Down mode, set PD bit in PCON register. The AT89C51ID2 enters the Power-Down mode upon execution of the instruction that sets PD bit. The instruction that sets PD bit is the last instruction executed.

Exiting Power-Down Mode

Note: If VCC was reduced during the Power-Down mode, do not exit Power-Down mode until VCC is restored to the normal operating level.

There are two ways to exit the Power-Down mode:

1. Generate an enabled external interrupt.
    –   The AT89C51ID2 provides capability to exit from Power-Down using INT0#, INT1#.
        Hardware clears PD bit in PCON register which starts the oscillator and restores the clocks to the CPU and peripherals. Using INTx# input, execution resumes when the input is released (see Figure 27). Execution resumes with the interrupt service routine. Upon completion of the interrupt service routine, program execution resumes with the instruction immediately following the instruction that activated Power-Down mode.

Note: The external interrupt used to exit Power-Down mode must be configured as level sensitive (INT0# and INT1#) and must be assigned the highest priority. In addition, the duration of the interrupt must be long enough to allow the oscillator to stabilize. The execution will only resume when the interrupt is deasserted.

Note: Exit from power-down by external interrupt does not affect the SFRs nor the internal RAM content.

Figure 27. Power-Down Exit Waveform Using INT1:0#
2. Generate a reset.
    –   A logic high on the RST pin clears PD bit in PCON register directly and asynchronously. This starts the oscillator and restores the clock to the CPU and peripherals. Program execution momentarily resumes with the instruction immediately following the instruction that activated Power-Down mode and may continue for a number of clock cycles before the internal reset algorithm takes control. Reset initializes the AT89C51ID2 and vectors the CPU to address 0000h.

Note: During the time that execution resumes, the internal RAM cannot be accessed; however, it is possible for the Port pins to be accessed. To avoid unexpected outputs at the Port

pins, the instruction immediately following the instruction that activated the Power-Down mode should not write to a Port pin or to the external RAM.

Note: Exit from power-down by reset redefines all the SFRs, but does not affect the internal RAM content.

Table 56. Pin Conditions in Special Operating Modes

Mode	Port 0	Port 1	Port 2	Port 3	Port 4	ALE	PSEN#
Reset	Floating	High	High	High	High	High	High

Power-Down (external code)	Floating	Data	Data	Data	Data	Low	Low

Registers

Table 57. PCON Register
PCON (S87:h) Power configuration Register

7	6	5	4	3	2	1	0
-	-	-	POF	GF1	GF0	PD	IDL

Bit Number	Bit Mnemonic	Description
7-5	-	**Reserved** The value read from these bits is indeterminate. Do not set these bits.
4	POF	**Power-Off Flag** Cleared to recognize next reset type. Set by hardware when VCC rises from 0 to its nominal voltage. Can also be set by software.
3	GF1	**General Purpose flag 1** One use is to indicate whether an interrupt occurred during normal operation or during Idle mode.
2	GF0	**General Purpose flag 0** One use is to indicate whether an interrupt occurred during normal operation or during Idle mode.
1	PD	**Power-Down Mode bit** Cleared by hardware when an interrupt or reset occurs. Set to activate the Power-Down mode. If IDL and PD are both set, PD takes precedence.
0	IDL	**Idle Mode bit** Cleared by hardware when an interrupt or reset occurs. Set to activate the Idle mode. If IDL and PD are both set, PD takes precedence.

Reset Value= XXXX 0000b

Keyboard Interface

The AT89C51ID2 implements a keyboard interface allowing the connection of a 8 x n matrix keyboard. It is based on 8 inputs with programmable interrupt capability on both high or low level. These inputs are available as alternate function of P1 and allow to exit from idle and power down modes.

The keyboard interface interfaces with the C51 core through 3 special function registers: KBLS, the Keyboard Level Selection register (Table 60), KBE, The Keyboard interrupt Enable register (Table 59), and KBF, the Keyboard Flag register (Table 58).

Interrupt

The keyboard inputs are considered as 8 independent interrupt sources sharing the same interrupt vector. An interrupt enable bit (KBD in IE1) allows global enable or disable of the keyboard interrupt (see Figure 28). As detailed in Figure 29 each keyboard input has the capability to detect a programmable level according to KBLS. x bit value. Level detection is then reported in interrupt flags KBF. x that can be masked by software using KBE. x bits.
This structure allow keyboard arrangement from 1 by n to 8 by n matrix and allow usage of P1 inputs for other purpose.

Figure 28. Keyboard Interface Block Diagram
Figure 29. Keyboard Input Circuitry
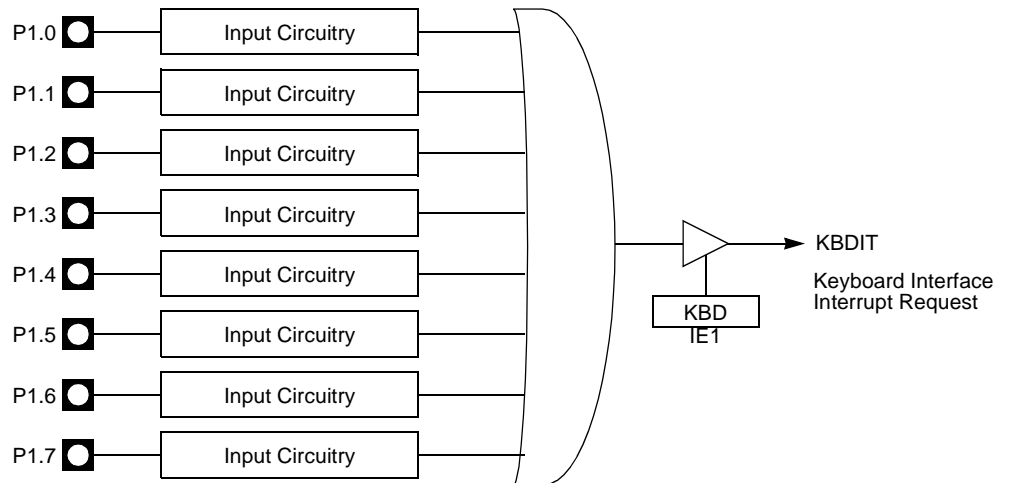

Power Reduction Mode

P1 inputs allow exit from idle and power down modes as detailed in Section "Power Management", page 73.

2-wire Interface (TWI)
This section describes the 2-wire interface. The 2-wire bus is a bi-directional 2-wire serial communication standard. It is designed primarily for simple but efficient integrated circuit (IC) control. The system is comprised of two lines, SCL (Serial Clock) and SDA (Serial Data) that carry information between the ICs connected to them. The serial data transfer is limited to 400 Kbit/s in standard mode. Various communication configuration can be designed using this bus. Figure 30 shows a typical 2-wire bus configuration. All the devices connected to the bus can be master and slave.

Figure 30. 2-wire Bus Configuration
Figure 31. Block Diagram
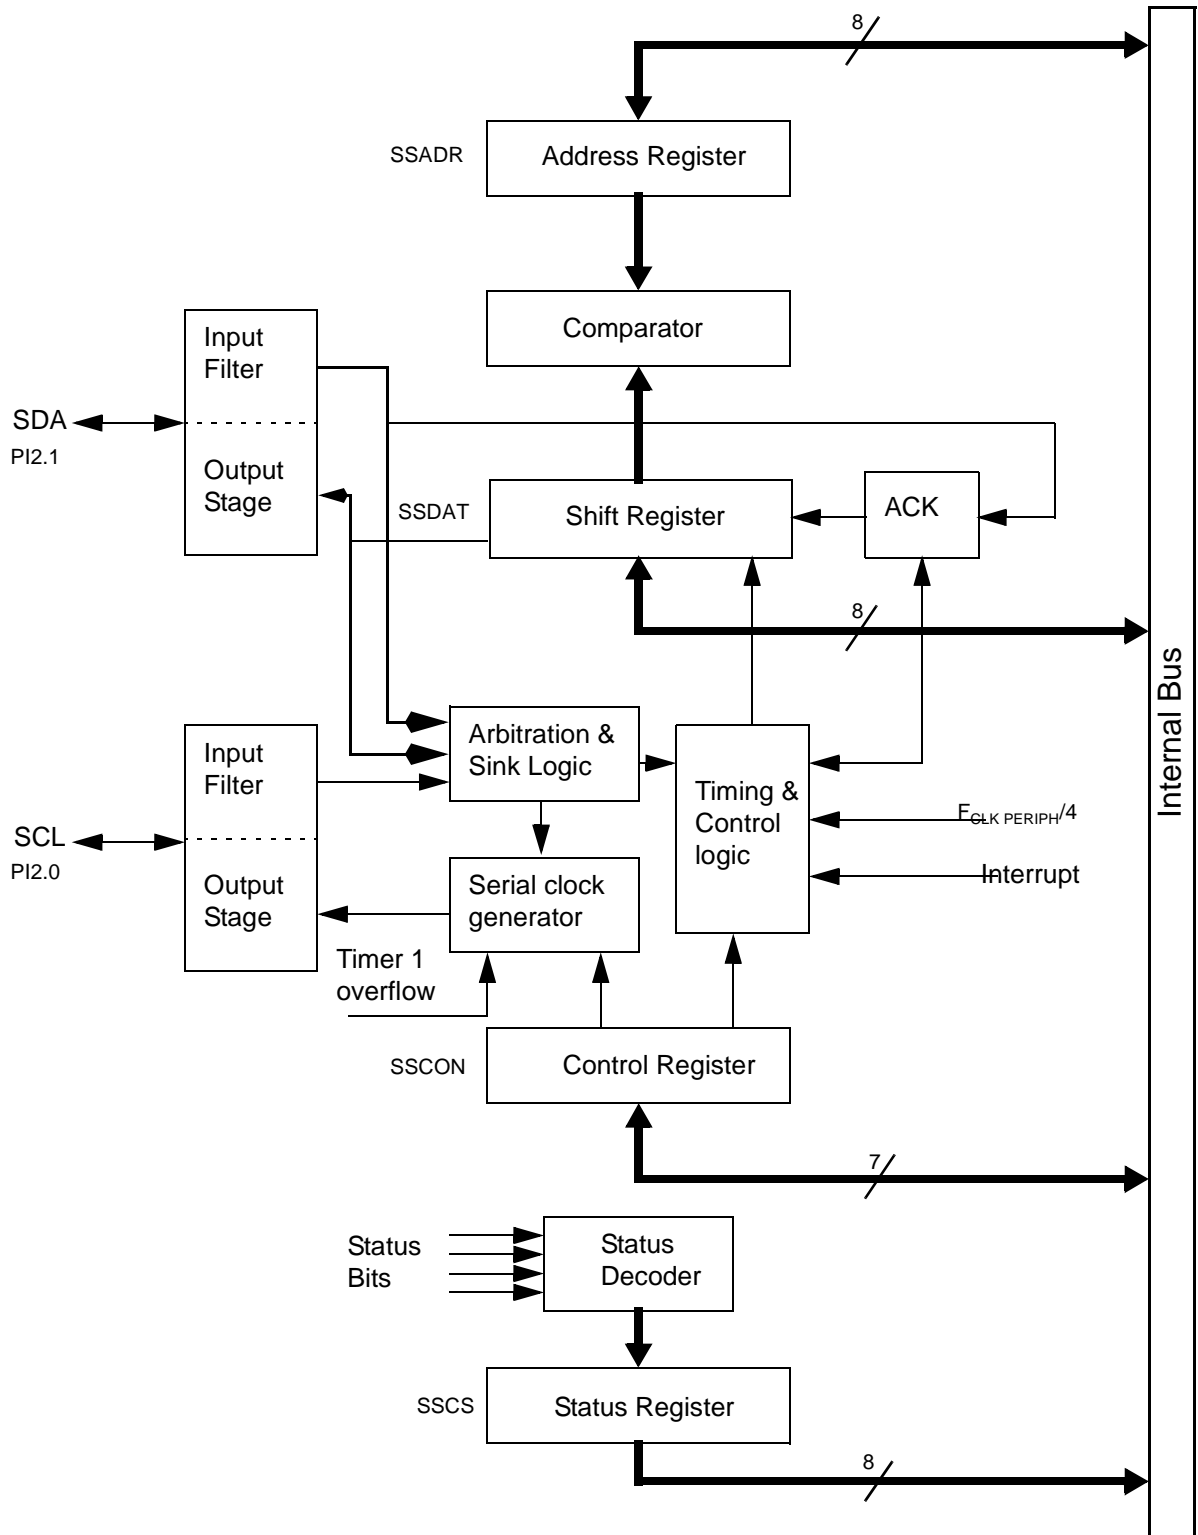

Description

The CPU interfaces to the 2-wire logic via the following four 8-bit special function regis-ters: the Synchronous Serial Control register (SSCON; Table 70), the Synchronous Serial Data register (SSDAT; Table 71), the Synchronous Serial Control and Status reg-ister (SSCS; Table 72) and the Synchronous Serial Address register (SSADR Table 75).

SSCON is used to enable the TWI interface, to program the bit rate (see Table 63), to enable slave modes, to acknowledge or not a received data, to send a START or a STOP condition on the 2-wire bus, and to acknowledge a serial interrupt. A hardware reset disables the TWI module.

SSCS contains a status code which reflects the status of the 2-wire logic and the 2-wire bus. The three least significant bits are always zero. The five most significant bits con-tains the status code. There are 26 possible status codes. When SSCS contains F8h, no relevant state information is available and no serial interrupt is requested. A valid sta-tus code is available in SSCS one machine cycle after SI is set by hardware and is still present one machine cycle after SI has been reset by software. to Table 69. give the status for the master modes and miscellaneous states.

SSDAT contains a byte of serial data to be transmitted or a byte which has just been received. It is addressable while it is not in process of shifting a byte. This occurs when 2-wire logic is in a defined state and the serial interrupt flag is set. Data in SSDAT remains stable as long as SI is set. While data is being shifted out, data on the bus is simultaneously shifted in; SSDAT always contains the last byte present on the bus.

SSADR may be loaded with the 7-bit slave address (7 most significant bits) to which the TWI module will respond when programmed as a slave transmitter or receiver. The LSB is used to enable general call address (00h) recognition.

Figure 32 shows how a data transfer is accomplished on the 2-wire bus.

Figure 32. Complete Data Transfer on 2-wire Bus
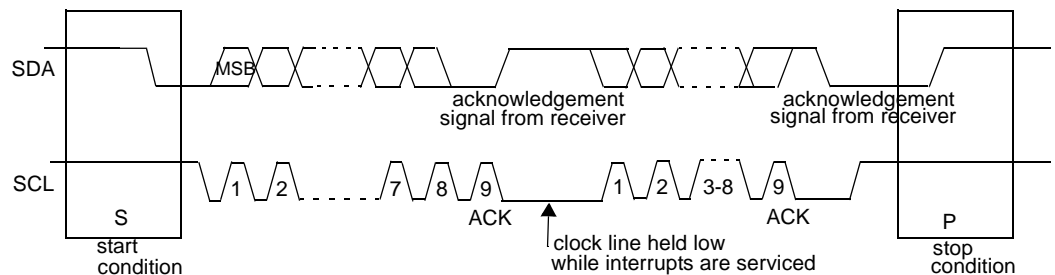

The four operating modes are:

• Master Transmitter

• Master Receiver

• Slave transmitter

• Slave receiver

Data transfer in each mode of operation is shown in Table to Table 69 and Figure 33. to Figure 36.. These figures contain the following abbreviations:

S : START condition

R : Read bit (high level at SDA)

W: Write bit (low level at SDA)

A: Acknowledge bit (low level at SDA)

$\overline{A}$: Not acknowledge bit (high level at SDA)

Data: 8-bit data byte

P : STOP condition

In Figure 33 to Figure 36, circles are used to indicate when the serial interrupt flag is set. The numbers in the circles show the status code held in SSCS. At these points, a service routine must be executed to continue or complete the serial transfer. These service routines are not critical since the serial transfer is suspended until the serial interrupt flag is cleared by software.

When the serial interrupt routine is entered, the status code in SSCS is used to branch to the appropriate service routine. For each status code, the required software action and details of the following serial transfer are given in Table to Table 69.

Master Transmitter Mode

In the master transmitter mode, a number of data bytes are transmitted to a slave receiver (Figure 33). Before the master transmitter mode can be entered, SSCON must be initialised as follows:

Table 61. SSCON Initialization

CR2	SSIE	STA	STO	SI	AA	CR1	CR0
bit rate	1	0	0	0	X	bit rate	bit rate

CR0, CR1 and CR2 define the internal serial bit rate if external bit rate generator is not used. SSIE must be set to enable TWI. STA, STO and SI must be cleared.

The master transmitter mode may now be entered by setting the STA bit. The 2-wire logic will now test the 2-wire bus and generate a START condition as soon as the bus becomes free. When a START condition is transmitted, the serial interrupt flag (SI bit in SSCON) is set, and the status code in SSCS will be 08h. This status must be used to vector to an interrupt routine that loads SSDAT with the slave address and the data direction bit (SLA+W).

When the slave address and the direction bit have been transmitted and an acknowledgement bit has been received, SI is set again and a number of status code in SSCS are possible. There are 18h, 20h or 38h for the master mode and also 68h, 78h or B0h if the slave mode was enabled (AA=logic 1). The appropriate action to be taken for each of these status code is detailed in Table . This scheme is repeated until a STOP condition is transmitted.

SSIE, CR2, CR1 and CR0 are not affected by the serial transfer and are referred to Table 7 to Table 11. After a repeated START condition (state 10h) the TWI module may switch to the master receiver mode by loading SSDAT with SLA+R.

Master Receiver Mode

In the master receiver mode, a number of data bytes are received from a slave transmitter (Figure 34). The transfer is initialized as in the master transmitter mode. When the START condition has been transmitted, the interrupt routine must load SSDAT with the 7-bit slave address and the data direction bit (SLA+R). The serial interrupt flag SI must then be cleared before the serial transfer can continue.

When the slave address and the direction bit have been transmitted and an acknowledgement bit has been received, the serial interrupt flag is set again and a number of status code in SSCS are possible. There are 40h, 48h or 38h for the master mode and also 68h, 78h or B0h if the slave mode was enabled (AA=logic 1). The appropriate action to be taken for each of these status code is detailed in Table . This scheme is repeated until a STOP condition is transmitted.

SSIE, CR2, CR1 and CR0 are not affected by the serial transfer and are referred to Table 7 to Table 11. After a repeated START condition (state 10h) the TWI module may switch to the master transmitter mode by loading SSDAT with SLA+W.

Slave Receiver Mode

In the slave receiver mode, a number of data bytes are received from a master transmitter (Figure 35). To initiate the slave receiver mode, SSADR and SSCON must be loaded as follows:

Table 62. SSADR: Slave Receiver Mode Initialization

A6	A5	A4	A3	A2	A1	A0	GC
own slave address							

The upper 7 bits are the address to which the TWI module will respond when addressed by a master. If the LSB (GC) is set the TWI module will respond to the general call address (00h); otherwise it ignores the general call address.

Table 63. SSCON: Slave Receiver Mode Initialization

CR2	SSIE	STA	STO	SI	AA	CR1	CR0
bit rate	1	0	0	0	1	bit rate	bit rate

CR0, CR1 and CR2 have no effect in the slave mode. SSIE must be set to enable the TWI. The AA bit must be set to enable the own slave address or the general call address acknowledgement. STA, STO and SI must be cleared.

When SSADR and SSCON have been initialised, the TWI module waits until it is addressed by its own slave address followed by the data direction bit which must be at logic 0 (W) for the TWI to operate in the slave receiver mode. After its own slave address and the W bit have been received, the serial interrupt flag is set and a valid status code can be read from SSCS. This status code is used to vector to an interrupt service routine.The appropriate action to be taken for each of these status code is detailed in Table . The slave receiver mode may also be entered if arbitration is lost while TWI is in the master mode (states 68h and 78h).

If the AA bit is reset during a transfer, TWI module will return a not acknowledge (logic 1) to SDA after the next received data byte. While AA is reset, the TWI module does not respond to its own slave address. However, the 2-wire bus is still monitored and address recognition may be resume at any time by setting AA. This means that the AA bit may be used to temporarily isolate the module from the 2-wire bus.

Slave Transmitter Mode

In the slave transmitter mode, a number of data bytes are transmitted to a master receiver (Figure 36). Data transfer is initialized as in the slave receiver mode. When SSADR and SSCON have been initialized, the TWI module waits until it is addressed by

its own slave address followed by the data direction bit which must be at logic 1 (R) for TWI to operate in the slave transmitter mode. After its own slave address and the R bit have been received, the serial interrupt flag is set and a valid status code can be read from SSCS. This status code is used to vector to an interrupt service routine. The appropriate action to be taken for each of these status code is detailed in Table . The slave transmitter mode may also be entered if arbitration is lost while the TWI module is in the master mode.

If the AA bit is reset during a transfer, the TWI module will transmit the last byte of the transfer and enter state C0h or C8h. the TWI module is switched to the not addressed slave mode and will ignore the master receiver if it continues the transfer. Thus the master receiver receives all 1's as serial data. While AA is reset, the TWI module does not respond to its own slave address. However, the 2-wire bus is still monitored and address recognition may be resume at any time by setting AA. This means that the AA bit may be used to temporarily isolate the TWI module from the 2-wire bus.

Miscellaneous States

There are two SSCS codes that do not correspond to a define TWI hardware state (Table 69). These codes are discuss hereafter.

Status F8h indicates that no relevant information is available because the serial interrupt flag is not set yet. This occurs between other states and when the TWI module is not involved in a serial transfer.

Status 00h indicates that a bus error has occurred during a TWI serial transfer. A bus error is caused when a START or a STOP condition occurs at an illegal position in the format frame. Examples of such illegal positions happen during the serial transfer of an address byte, a data byte, or an acknowledge bit. When a bus error occurs, SI is set. To recover from a bus error, the STO flag must be set and SI must be cleared. This causes the TWI module to enter the not addressed slave mode and to clear the STO flag (no other bits in SSCON are affected). The SDA and SCL lines are released and no STOP condition is transmitted.

Notes

the TWI module interfaces to the external 2-wire bus via two port pins: SCL (serial clock line) and SDA (serial data line). To avoid low level asserting on these lines when the TWI module is enabled, the output latches of SDA and SLC must be set to logic 1.

Serial Port Interface (SPI)

The Serial Peripheral Interface module (SPI) allows full-duplex, synchronous, serial communication between the MCU and peripheral devices, including other MCUs.

Features

Features of the SPI module include the following:
- Full-duplex, three-wire synchronous transfers
- Master or Slave operation
- Eight programmable Master clock rates
- Serial clock with programmable polarity and phase
- Master Mode fault error flag with MCU interrupt capability
- Write collision flag protection

Signal Description

Figure 37 shows a typical SPI bus configuration using one Master controller and many Slave peripherals. The bus is made of three wires connecting all the devices:

Figure 37. SPI Master/Slaves interconnection
The Master device selects the individual Slave devices by using four pins of a parallel port to control the four $\overline{SS}$ pins of the Slave devices.

Master Output Slave Input (MOSI)

This 1-bit signal is directly connected between the Master Device and a Slave Device. The MOSI line is used to transfer data in series from the Master to the Slave. Therefore, it is an output signal from the Master, and an input signal to a Slave. A byte (8-bit word) is transmitted most significant bit (MSB) first, least significant bit (LSB) last.

Master Input Slave Output (MISO)

This 1-bit signal is directly connected between the Slave Device and a Master Device. The MISO line is used to transfer data in series from the Slave to the Master. Therefore, it is an output signal from the Slave, and an input signal to the Master. A byte (8-bit word) is transmitted most significant bit (MSB) first, least significant bit (LSB) last.

SPI Serial Clock (SCK)

This signal is used to synchronize the data movement both in and out the devices through their MOSI and MISO lines. It is driven by the Master for eight clock cycles which allows to exchange one byte on the serial lines.

Slave Select ($\overline{SS}$)

Each Slave peripheral is selected by one Slave Select pin ($\overline{SS}$). This signal must stay low for any message for a Slave. It is obvious that only one Master ($\overline{SS}$ high level) can

drive the network. The Master may select each Slave device by software through port pins (Figure 37). To prevent bus conflicts on the MISO line, only one slave should be selected at a time by the Master for a transmission.

In a Master configuration, the $\overline{SS}$ line can be used in conjunction with the MODF flag in the SPI Status register (SPSTA) to prevent multiple masters from driving MOSI and SCK (See Error conditions).

A high level on the $\overline{SS}$ pin puts the MISO line of a Slave SPI in a high-impedance state.

The $\overline{SS}$ pin could be used as a general purpose if the following conditions are met:

- The device is configured as a Master and the SSDIS control bit in SPCON is set. This kind of configuration can be found when only one Master is driving the network and there is no way that the $\overline{SS}$ pin could be pulled low. Therefore, the MODF flag in the SPSTA will never be set[1].

- The Device is configured as a Slave with CPHA and SSDIS control bits set[2] This kind of configuration can happen when the system comprises one Master and one Slave only. Therefore, the device should always be selected and there is no reason that the Master uses the $\overline{SS}$ pin to select the communicating Slave device.

Note: 1. Clearing SSDIS control bit does not clear MODF.

2. Special care should be taken not to set SSDIS control bit when CPHA ='0' because in this mode, the $\overline{SS}$ is used to start the transmission.

Baud rate

In Master mode, the baud rate can be selected from a baud rate generator which is controlled by three bits in the SPCON register: SPR2, SPR1 and SPR0.The Master clock is chosen from one of seven clock rates resulting from the division of the internal clock by 2, 4, 8, 16, 32, 64 or 128.

Table 76 gives the different clock rates selected by SPR2:SPR1:SPR0:

Table 76. SPI Master Baud Rate Selection

SPR2	SPR1	SPR0	Clock Rate	Baud rate divisor (BD)
0	0	0	Don't Use	No BRG
0	0	1	$F_{CLK\ PERIPH}$ /4	4
0	1	0	$F_{CLK\ PERIPH}$ / 8	8
0	1	1	$F_{CLK\ PERIPH}$ /16	16
1	0	0	$F_{CLK\ PERIPH}$ /32	32
1	0	1	$F_{CLK\ PERIPH}$ /64	64
1	1	0	$F_{CLK\ PERIPH}$ /128	128
1	1	1	Don't Use	No BRG

Functional Description   Figure 38 shows a detailed structure of the SPI module.

Figure 38. SPI Module Block Diagram
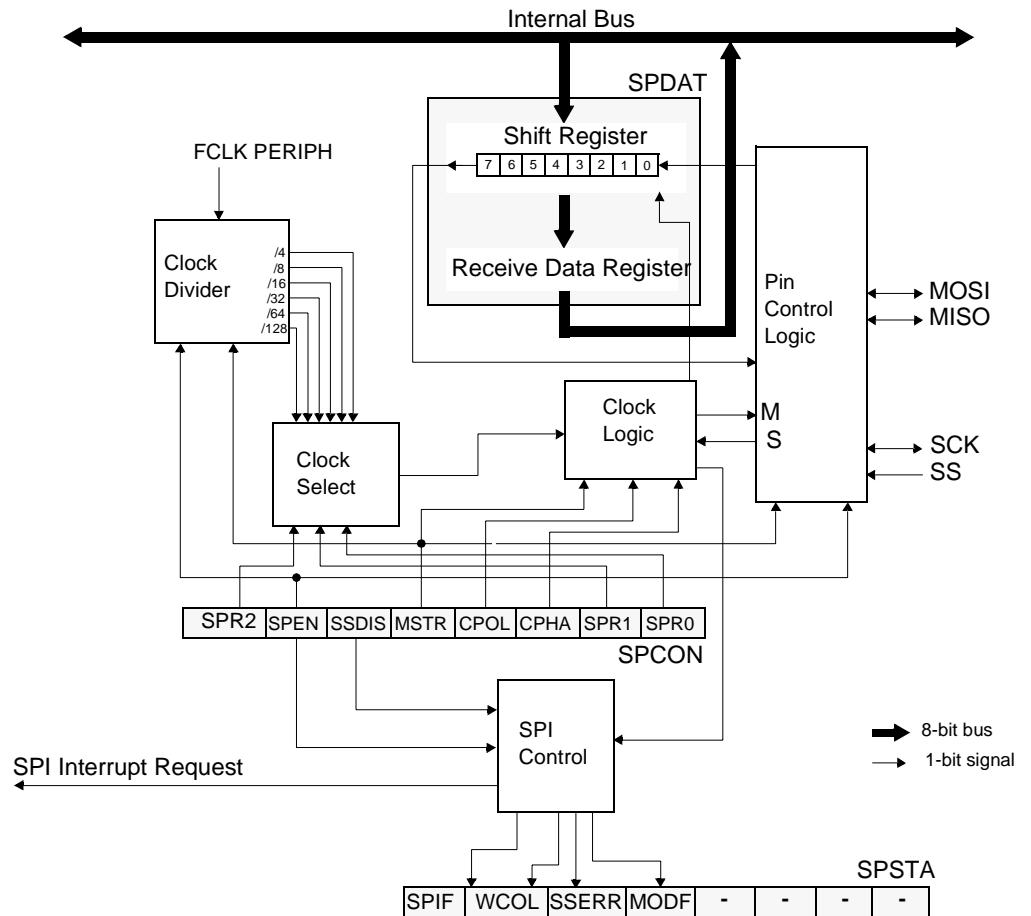

Operating Modes   The Serial Peripheral Interface can be configured as one of the two modes: Master mode or Slave mode. The configuration and initialization of the SPI module is made through one register:

• The Serial Peripheral CONtrol register (SPCON)

Once the SPI is configured, the data exchange is made using:

• SPCON
• The Serial Peripheral STAtus register (SPSTA)
• The Serial Peripheral DATa register (SPDAT)

During an SPI transmission, data is simultaneously transmitted (shifted out serially) and received (shifted in serially). A serial clock line (SCK) synchronizes shifting and sampling on the two serial data lines (MOSI and MISO). A Slave Select line (SS) allows individual selection of a Slave SPI device; Slave devices that are not selected do not interfere with SPI bus activities.

When the Master device transmits data to the Slave device via the MOSI line, the Slave device responds by sending data to the Master device via the MISO line. This implies full-duplex transmission with both data out and data in synchronized with the same clock (Figure 39).

Figure 39. Full-Duplex Master-Slave Interconnection
Master mode

The SPI operates in Master mode when the Master bit, MSTR [1], in the SPCON register is set. Only one Master SPI device can initiate transmissions. Software begins the transmission from a Master SPI module by writing to the Serial Peripheral Data Register (SPDAT). If the shift register is empty, the byte is immediately transferred to the shift register. The byte begins shifting out on MOSI pin under the control of the serial clock, SCK. Simultaneously, another byte shifts in from the Slave on the Master's MISO pin. The transmission ends when the Serial Peripheral transfer data flag, SPIF, in SPSTA becomes set. At the same time that SPIF becomes set, the received byte from the Slave is transferred to the receive data register in SPDAT. Software clears SPIF by reading the Serial Peripheral Status register (SPSTA) with the SPIF bit set, and then reading the SPDAT.

Slave mode

The SPI operates in Slave mode when the Master bit, MSTR [2], in the SPCON register is cleared. Before a data transmission occurs, the Slave Select pin, SS, of the Slave device must be set to'0'. SS must remain low until the transmission is complete.

In a Slave SPI module, data enters the shift register under the control of the SCK from the Master SPI module. After a byte enters the shift register, it is immediately transferred to the receive data register in SPDAT, and the SPIF bit is set. To prevent an overflow condition, Slave software must then read the SPDAT before another byte enters the shift register [3]. A Slave SPI must complete the write to the SPDAT (shift register) at least one bus cycle before the Master SPI starts a transmission. If the write to the data register is late, the SPI transmits the data already in the shift register from the previous transmission.

Transmission Formats

Software can select any of four combinations of serial clock (SCK) phase and polarity using two bits in the SPCON: the Clock POLarity (CPOL [4]) and the Clock PHAse (CPHA[4]). CPOL defines the default SCK line level in idle state. It has no significant effect on the transmission format. CPHA defines the edges on which the input data are sampled and the edges on which the output data are shifted (Figure 40 and Figure 41). The clock phase and polarity should be identical for the Master SPI device and the communicating Slave device.

1. The SPI module should be configured as a Master before it is enabled (SPEN set). Also the Master SPI should be configured before the Slave SPI.
2. The SPI module should be configured as a Slave before it is enabled (SPEN set).
3. The maximum frequency of the SCK for an SPI configured as a Slave is the bus clock speed.
4. Before writing to the CPOL and CPHA bits, the SPI should be disabled (SPEN ='0').

Capture point

Figure 42. CPHA/$\overline{\text{SS}}$ Timing

MISO/MOSI: Byte 1 Byte 2 Byte 3

Master SS

Slave SS (CPHA = 0)

Slave SS (CPHA = 1)
As shown in Figure 40, the first SCK edge is the MSB capture strobe. Therefore the Slave must begin driving its data before the first SCK edge, and a falling edge on the $\overline{\text{SS}}$ pin is used to start the transmission. The $\overline{\text{SS}}$ pin must be toggled high and then low between each byte transmitted (Figure 42).

Figure 41 shows an SPI transmission in which CPHA is '1'. In this case, the Master begins driving its MOSI pin on the first SCK edge. Therefore the Slave uses the first SCK edge as a start transmission signal. The $\overline{\text{SS}}$ pin can remain low between transmissions (Figure 42). This format may be preffered in systems having only one Master and only one Slave driving the MISO data line.

Error conditions   The following flags in the SPSTA signal SPI error conditions:

Mode Fault (MODF)   Mode Fault error in Master mode SPI indicates that the level on the Slave Select ($\overline{SS}$) pin is inconsistent with the actual mode of the device. MODF is set to warn that there may have a multi-master conflict for system control. In this case, the SPI system is affected in the following ways:

- An SPI receiver/error CPU interrupt request is generated,
- The SPEN bit in SPCON is cleared. This disable the SPI,
- The MSTR bit in SPCON is cleared

When $\overline{SS}$ DISable (SSDIS) bit in the SPCON register is cleared, the MODF flag is set when the $\overline{SS}$ signal becomes '0'.

However, as stated before, for a system with one Master, if the $\overline{SS}$ pin of the Master device is pulled low, there is no way that another Master attempt to drive the network. In this case, to prevent the MODF flag from being set, software can set the SSDIS bit in the SPCON register and therefore making the $\overline{SS}$ pin as a general purpose I/O pin.

Clearing the MODF bit is accomplished by a read of SPSTA register with MODF bit set, followed by a write to the SPCON register. SPEN Control bit may be restored to its original set state after the MODF bit has been cleared.

Write Collision (WCOL)   A Write Collision (WCOL) flag in the SPSTA is set when a write to the SPDAT register is done during a transmit sequence.

WCOL does not cause an interruption, and the transfer continues uninterrupted.

Clearing the WCOL bit is done through a software sequence of an access to SPSTA and an access to SPDAT.

Overrun Condition   An overrun condition occurs when the Master device tries to send several data bytes and the Slave devise has not cleared the SPIF bit issuing from the previous data byte transmitted. In this case, the receiver buffer contains the byte sent after the SPIF bit was last cleared. A read of the SPDAT returns this byte. All others bytes are lost.

This condition is not detected by the SPI peripheral.

Interrupts   Two SPI status flags can generate a CPU interrupt requests:

Table 77. SPI Interrupts

Flag	Request
SPIF (SP data transfer)	SPI Transmitter Interrupt request
MODF (Mode Fault)	SPI Receiver/Error Interrupt Request (if SSDIS ='0')

Serial Peripheral data transfer flag, SPIF: This bit is set by hardware when a transfer has been completed. SPIF bit generates transmitter CPU interrupt requests.

Mode Fault flag, MODF: This bit becomes set to indicate that the level on the SS is inconsistent with the mode of the SPI. MODF with SSDIS reset, generates receiver/error CPU interrupt requests. When SSDIS is set, no MODF interrupt request is generated.

Figure 43 gives a logical view of the above statements.

Figure 43. SPI Interrupt Requests Generation
Registers

There are three registers in the module that provide control, status and data storage functions. These registers are describes in the following paragraphs.

Serial Peripheral Control register (SPCON)

• The Serial Peripheral Control Register does the following:

• Selects one of the Master clock rates,

• Configure the SPI module as Master or Slave,

• Selects serial clock polarity and phase,

• Enables the SPI module,

• Frees the SS pin for a general purpose

Table 78 describes this register and explains the use of each bit.

Table 78. SPCON Register

SPCON - Serial Peripheral Control Register (0C3H)

7	6	5	4	3	2	1	0
SPR2	SPEN	SSDIS	MSTR	CPOL	CPHA	SPR1	SPR0

Bit Number	Bit Mnemonic	Description
7	SPR2	**Serial Peripheral Rate 2** Bit with SPR1 and SPR0 define the clock rate.
6	SPEN	**Serial Peripheral Enable** Cleared to disable the SPI interface. Set to enable the SPI interface.
5	SSDIS	$\overline{\text{SS}}$ **Disable** Cleared to enable SS# in both Master and Slave modes. Set to disable SS# in both Master and Slave modes. In Slave mode, this bit has no effect if CPHA ='0'. When SSDIS is set, no MODF interrupt request is generated.
5	MSTR	**Serial Peripheral Master** Cleared to configure the SPI as a Slave. Set to configure the SPI as a Master.
4	CPOL	**Clock Polarity** Cleared to have the SCK set to'0' in idle state. Set to have the SCK set to'1' in idle low.
3	CPHA	**Clock Phase** Cleared to have the data sampled when the SCK leaves the idle state (see CPOL). Set to have the data sampled when the SCK returns to idle state (see CPOL).

Bit Number	Bit Mnemonic	Description
2	SPR1	**SPR2** **SPR1** **SPR0** **Serial Peripheral Rate** 0 0 0 Invalid 0 0 1 $F_{CLK\ PERIPH}$/4 0 1 0 $F_{CLK\ PERIPH}$/8
1	SPR0	0 1 1 $F_{CLK\ PERIPH}$/16 1 0 0 $F_{CLK\ PERIPH}$/32 1 0 1 $F_{CLK\ PERIPH}$/64 1 1 0 $F_{CLK\ PERIPH}$/128 1 1 1 Invalid

Reset Value= 0001 0100b

Not bit addressable

Serial Peripheral Status Register (SPSTA)

The Serial Peripheral Status Register contains flags to signal the following conditions:

- Data transfer complete
- Write collision
- Inconsistent logic level on $\overline{SS}$ pin (mode fault error)

Table 79 describes the SPSTA register and explains the use of every bit in the register.

Table 79. SPSTA Register

SPSTA - Serial Peripheral Status and Control register (0C4H)

7	6	5	4	3	2	1	0
SPIF	WCOL	SSERR	MODF	-	-	-	-

Bit Number	Bit Mnemonic	Description
7	SPIF	**Serial Peripheral data transfer flag** Cleared by hardware to indicate data transfer is in progress or has been approved by a clearing sequence. Set by hardware to indicate that the data transfer has been completed.
6	WCOL	**Write Collision flag** Cleared by hardware to indicate that no collision has occurred or has been approved by a clearing sequence. Set by hardware to indicate that a collision has been detected.
5	SSERR	**Synchronous Serial Slave Error flag** Set by hardware when $\overline{SS}$ is deasserted before the end of a received data. Cleared by disabling the SPI (clearing SPEN bit in SPCON).
4	MODF	**Mode Fault** Cleared by hardware to indicate that the $\overline{SS}$ pin is at appropriate logic level, or has been approved by a clearing sequence. Set by hardware to indicate that the $\overline{SS}$ pin is at inappropriate logic level.
3	-	**Reserved** The value read from this bit is indeterminate. Do not set this bit

Bit Number	Bit Mnemonic	Description
2	-	**Reserved** The value read from this bit is indeterminate. Do not set this bit
1	-	**Reserved** The value read from this bit is indeterminate. Do not set this bit.
0	-	**Reserved** The value read from this bit is indeterminate. Do not set this bit.

Reset Value= 00X0 XXXXb

Not Bit addressable

Serial Peripheral DATa register (SPDAT)

The Serial Peripheral Data Register (Table 80) is a read/write buffer for the receive data register. A write to SPDAT places data directly into the shift register. No transmit buffer is available in this model.

A Read of the SPDAT returns the value located in the receive buffer and not the content of the shift register.

Table 80. SPDAT Register

SPDAT - Serial Peripheral Data Register (0C5H)

7	6	5	4	3	2	1	0
R7	R6	R5	R4	R3	R2	R1	R0

Reset Value= Indeterminate

R7:R0: Receive data bits

SPCON, SPSTA and SPDAT registers may be read and written at any time while there is no on-going exchange. However, special care should be taken when writing to them while a transmission is on-going:

- Do not change SPR2, SPR1 and SPR0
- Do not change CPHA and CPOL
- Do not change MSTR
- Clearing SPEN would immediately disable the peripheral
- Writing to the SPDAT will cause an overflow

Hardware Watchdog Timer

The WDT is intended as a recovery method in situations where the CPU may be subjected to software upset. The WDT consists of a 14-bit counter and the WatchDog Timer ReSeT (WDTRST) SFR. The WDT is by default disabled from exiting reset. To enable the WDT, user must write 01EH and 0E1H in sequence to the WDTRST, SFR location 0A6H. When WDT is enabled, it will increment every machine cycle while the oscillator is running and there is no way to disable the WDT except through reset (either hardware reset or WDT overflow reset). When WDT overflows, it will drive an output RESET HIGH pulse at the RST-pin.

Using the WDT

To enable the WDT, user must write 01EH and 0E1H in sequence to the WDTRST, SFR location 0A6H. When WDT is enabled, the user needs to service it by writing to 01EH and 0E1H to WDTRST to avoid WDT overflow. The 14-bit counter overflows when it reaches 16383 (3FFFH) and this will reset the device. When WDT is enabled, it will increment every machine cycle while the oscillator is running. This means the user must reset the WDT at least every 16383 machine cycle. To reset the WDT the user must write 01EH and 0E1H to WDTRST. WDTRST is a write only register. The WDT counter cannot be read or written. When WDT overflows, it will generate an output RESET pulse at the RST-pin. The RESET pulse duration is 96 x $T_{CLK\ PERIPH}$, where $T_{CLK\ PERIPH} = 1/F_{CLK\ PERIPH}$. To make the best use of the WDT, it should be serviced in those sections of code that will periodically be executed within the time required to prevent a WDT reset.

To have a more powerful WDT, a 2^7 counter has been added to extend the Time-out capability, ranking from 16ms to 2s @ F_{OSCA} = 12MHz. To manage this feature, refer to WDTPRG register description, Table 81.

Table 81. WDTRST Register

Reset value = XXXX X000

WDT During Power Down and Idle

In Power Down mode the oscillator stops, which means the WDT also stops. While in Power Down mode the user does not need to service the WDT. There are 2 methods of exiting Power Down mode: by a hardware reset or via a level activated external interrupt which is enabled prior to entering Power Down mode. When Power Down is exited with hardware reset, servicing the WDT should occur as it normally should whenever the AT89C51ID2 is reset. Exiting Power Down with an interrupt is significantly different. The interrupt is held low long enough for the oscillator to stabilize. When the interrupt is brought high, the interrupt is serviced. To prevent the WDT from resetting the device while the interrupt pin is held low, the WDT is not started until the interrupt is pulled high. It is suggested that the WDT be reset during the interrupt service routine.

To ensure that the WDT does not overflow within a few states of exiting of powerdown, it is better to reset the WDT just before entering powerdown.

In the Idle mode, the oscillator continues to run. To prevent the WDT from resetting the AT89C51ID2 while in Idle mode, the user should always set up a timer that will periodically exit Idle, service the WDT, and re-enter Idle mode.

ONCE(TM) Mode (ON Chip Emulation)

The ONCE mode facilitates testing and debugging of systems using AT89C51ID2 without removing the circuit from the board. The ONCE mode is invoked by driving certain pins of the AT89C51ID2; the following sequence must be exercised:

• Pull ALE low while the device is in reset (RST high) and $\overline{PSEN}$ is high.

• Hold ALE low as RST is deactivated.

While the AT89C51ID2 is in ONCE mode, an emulator or test CPU can be used to drive the circuit Table 83 shows the status of the port pins during ONCE mode.

Normal operation is restored when normal reset is applied.

Table 83. External Pin Status during ONCE Mode

ALE	PSEN	Port 0	Port 1	Port 2	Port 3	Port I2	XTALA1/2	XTALB1/2
Weak pull-up	Weak pull-up	Float	Weak pull-up	Weak pull-up	Weak pull-up	Float	Active	Active

(a) "Once" is a registered trademark of Intel Corporation.

Power-off Flag

The power-off flag allows the user to distinguish between a "cold start" reset and a "warm start" reset.

A cold start reset is the one induced by V_{CC} switch-on. A warm start reset occurs while V_{CC} is still applied to the device and could be generated for example by an exit from power-down.

The power-off flag (POF) is located in PCON register (Table 84). POF is set by hardware when V_{CC} rises from 0 to its nominal voltage. The POF can be set or cleared by software allowing the user to determine the type of reset.

Table 84. PCON Register

6	SMOD0	**Serial port Mode bit 0** Cleared to select SM0 bit in SCON register. Set to select FE bit in SCON register.
5	-	**Reserved** The value read from this bit is indeterminate. Do not set this bit.
4	POF	**Power-Off Flag** Cleared to recognize next reset type. Set by hardware when V_{CC} rises from 0 to its nominal voltage. Can also be set by software.
3	GF1	**General purpose Flag** Cleared by user for general purpose usage. Set by user for general purpose usage.
2	GF0	**General purpose Flag** Cleared by user for general purpose usage. Set by user for general purpose usage.
1	PD	**Power-Down mode bit** Cleared by hardware when reset occurs. Set to enter power-down mode.
0	IDL	**Idle mode bit** Cleared by hardware when interrupt or reset occurs. Set to enter idle mode.

Reset Value = 00X1 0000b
Not bit addressable

EEPROM Data Memory

The 2K bytes on-chip EEPROM memory block is located at addresses 0000h to 07FFh of the XRAM/ERAM memory space and is selected by setting control bits in the EECON register.

A read or write access to the EEPROM memory is done with a MOVX instruction.

Write Data

Data is written by byte to the EEPROM memory block as for an external RAM memory.

The following procedure is used to write to the EEPROM memory:

- Check EEBUSY flag
- If the user application interrupts routines use XRAM memory space: Save and disable interrupts.
- Load DPTR with the address to write
- Store A register with the data to be written
- Set bit EEE of EECON register
- Execute a MOVX @DPTR, A
- Clear bit EEE of EECON register
- Restore interrupts.
- EEBUSY flag in EECON is then set by hardware to indicate that programming is in progress and that the EEPROM segment is not available for reading or writing.
- The end of programming is indicated by a hardware clear of the EEBUSY flag.

Figure 44 represents the optimal write sequence to the on-chip EEPROM data memory.

Figure 44. Recommended EEPROM Data Write Sequence

Reduced EMI Mode

The ALE signal is used to demultiplex address and data buses on port 0 when used with external program or data memory. Nevertheless, during internal code execution, ALE signal is still generated. In order to reduce EMI, ALE signal can be disabled by setting AO bit.

The AO bit is located in AUXR register at bit location 0. As soon as AO is set, ALE is no longer output but remains active during MOVX and MOVC instructions and external fetches. During ALE disabling, ALE pin is weakly pulled high.

1	EXTRAM	**EXTRAM bit** Cleared to access internal XRAM using movx @ Ri/ @ DPTR. Set to access external memory. Programmed by hardware after Power-up regarding Hardware Security Byte (HSB), default setting, XRAM selected.
0	AO	**ALE Output bit** Cleared, ALE is emitted at a constant rate of 1/6 the oscillator frequency (or 1/3 if X2 mode is used). (default) Set, ALE is active only during a MOVX or MOVC instruction is used.

Reset Value = XX00 10'HSB. XRAM'0b
Not bit addressable

Flash Memory

The Flash memory increases EPROM and ROM functionality with in-circuit electrical erasure and programming. It contains 64K bytes of program memory organized respectively in 512 pages of 128 bytes. This memory is both parallel and serial In-System Programmable (ISP). ISP allows devices to alter their own program memory in the actual end product under software control. A default serial loader (bootloader) program allows ISP of the Flash.

The programming **does not require** external dedicated programming voltage. The necessary high programming voltage is generated on-chip using the standard V_{CC} pins of the microcontroller.

Features

- Flash internal program memory.
- Boot vector allows user provided Flash loader code to reside anywhere in the Flash memory space. This configuration provides flexibility to the user.
- Default loader in Boot ROM allows programming via the serial port without the need of a user provided loader.
- Up to 64K byte external program memory if the internal program memory is disabled (EA = 0).
- Programming and erase voltage with standard power supply.
- Read/Programming/Erase:
- Byte-wise read without wait state
- Byte or page erase and programming (10 ms)
- Typical programming time (64K bytes) is 22s with on chip serial bootloader
- Parallel programming with 87C51 compatible hardware interface to programmer
- Programmable security for the code in the Flash
- 100k write cycles
- 10 years data retention

Flash Programming and Erasure

The 64K bytes Flash is programmed by bytes or by pages of 128 bytes. It is not necessary to erase a byte or a page before programming. The programming of a byte or a page includes a self erase before programming.

There are three methods of programming the Flash memory:

- First, the on-chip ISP bootloader may be invoked which will use low level routines to program the pages. The interface used for serial downloading of Flash is the UART.
- Second, the Flash may be programmed or erased in the end-user application by calling low-level routines through a common entry point in the Boot ROM.
- Third, the Flash may be programmed using the parallel method by using a conventional EPROM programmer. The parallel programming method used by these devices is similar to that used by EPROM 87C51 but it is not identical and the commercially available programmers need to have support for the AT89C51ID2. The bootloader and the Application Programming Interface (API) routines are located in the BOOT ROM.

Flash Registers and Memory Map

The AT89C51ID2 Flash memory uses several registers for his management:

- Hardware registers can only be accessed through the parallel programming modes which are handled by the parallel programmer.
- Software registers are in a special page of the Flash memory which can be accessed through the API or with the parallel programming modes. This page, called "Extra Flash Memory", is not in the internal Flash program memory addressing space.

Hardware Register

The only hardware register of the AT89C51ID2 is called Hardware Security Byte (HSB).

Table 87. Hardware Security Byte (HSB)

7	6	5	4	3	2	1	0
X2	BLJB	OSC	-	XRAM	LB2	LB1	LB0

Bit Number	Bit Mnemonic	Description
7	X2	**X2 Mode** Programmed to force X2 mode (6 clocks per instruction) Unprogrammed to force X1 mode, Standard Mode. (Default)
6	BLJB	**Boot Loader Jump Bit** Unprogrammed this bit to start the user's application on next reset at address 0000h. Programmed this bit to start the boot loader at address F800h (Default).
5	OSC	**Oscillator Bit** Programmed to allow oscillator B at startup Unprogrammed this bit to allow oscillator A at startup (Default).
4	-	**Reserved**
3	XRAM	**XRAM config bit (only programmable by programmer tools)** Programmed to inhibit XRAM Unprogrammed, this bit to valid XRAM (Default)
2-0	LB2-0	**User Memory Lock Bits (only programmable by programmer tools)** See Table 88

Boot Loader Jump Bit (BLJB)

One bit of the HSB, the BLJB bit, is used to force the boot address:

- When this bit is set the boot address is 0000h.
- When this bit is reset the boot address is F800h. By default, this bit is cleared and the ISP is enabled.

Flash Memory Lock Bits

The three lock bits provide different levels of protection for the on-chip code and data, when programmed as shown in Table 88.

Table 88. Program Lock Bits

Program Lock Bits				
Security level	LB0	LB1	LB2	Protection description
1	U	U	U	No program lock features enabled.
2	P	U	U	MOVC instruction executed from external program memory is disabled from fetching code bytes from internal memory, $\overline{EA}$ is sampled and latched on reset, and further parallel programming of the on chip code memory is disabled. ISP and software programming with API are still allowed. Writing EEprom Data from external parallel programmer is disabled but still allowed from internal code execution.
3	X	P	U	Same as 2, also verify code memory through parallel programming interface is disabled. Writing And Reading EEPROM Data from external parallel programmer is disabled but still allowed from internal code execution..
4	X	X	P	Same as 3, also external execution is disabled. (Default)

Note: U: unprogrammed or "one" level.
       P: programmed or "zero" level.
       X: do not care
       WARNING: Security level 2 and 3 should only be programmed after Flash and code verification.

These security bits protect the code access through the parallel programming interface. They are set by default to level 4. The code access through the ISP is still possible and is controlled by the "software security bits" which are stored in the extra Flash memory accessed by the ISP firmware.

To load a new application with the parallel programmer, a chip erase must first be done. This will set the HSB in its inactive state and will erase the Flash memory. The part reference can always be read using Flash parallel programming modes.

Default Values

The default value of the HSB provides parts ready to be programmed with ISP:

- BLJB: Programmed force ISP operation.
- X2: Unprogrammed to force X1 mode (Standard Mode).
- XRAM: Unprogrammed to valid XRAM
- LB2-0: Security level four to protect the code from a parallel access with maximum security.

Software Registers

Several registers are used, in factory and by parallel programmers. These values are used by Atmel ISP.

These registers are in the "Extra Flash Memory" part of the Flash memory. This block is also called "XAF" or eXtra Array Flash. They are accessed in the following ways:

- Commands issued by the parallel memory programmer.
- Commands issued by the ISP software.
- Calls of API issued by the application software.

Several software registers described in Table 89.

Table 89. Default Values

Mnemonic	Definition	Default value	Description
SBV	Software Boot Vector	FCh	
HSB	Copy of the Hardware security byte	101x 1011b	
BSB	Boot Status Byte	0FFh	
SSB	Software Security Byte	FFh	
	Copy of the Manufacturer Code	58h	ATMEL
	Copy of the Device ID #1: Family Code	D7h	C51 X2, Electrically Erasable
	Copy of the Device ID #2: memories size and type	ECh	AT89C51ID2 64KB
	Copy of the Device ID #3: name and revision	EFh	AT89C51ID2 64KB, Revision 0

After programming the part by ISP, the BSB must be cleared (00h) in order to allow the application to boot at 0000h.

The content of the Software Security Byte (SSB) is described in Table 89 and Table 92.

To assure code protection from a parallel access, the HSB must also be at the required level.

Table 90. Software Security Byte

Table 91.

7	6	5	4	3	2	1	0
-	-	-	-	-	-	LB1	LB0

Bit Number	Bit Mnemonic	Description
7	-	**Reserved** Do not clear this bit.
6	-	**Reserved** Do not clear this bit.
5	-	**Reserved** Do not clear this bit.
4	-	**Reserved** Do not clear this bit.
3	-	**Reserved** Do not clear this bit.
2	-	**Reserved** Do not clear this bit.
1-0	LB1-0	User Memory Lock Bits See Table 92

The two lock bits provide different levels of protection for the on-chip code and data, when programmed as shown to Table 92.

Table 92. Program Lock bits of the SSB

Program Lock Bits			
Security level	**LB0**	**LB1**	**Protection description**
1	U	U	No program lock features enabled.
2	P	U	ISP programming of the Flash is disabled.
3	X	P	Same as 2, also verify through ISP programming interface is disabled.

Note: U: unprogrammed or "one" level.
          P: programmed or "zero" level.
          X: do not care
          WARNING: Security level 2 and 3 should only be programmed after Flash and code verification.

Flash Memory Status   AT89C51ID2 parts are delivered in standard with the ISP rom bootloader.

After ISP or parallel programming, the possible contents of the Flash memory are summarized on the figure below:

Figure 46. Flash memory possible contents
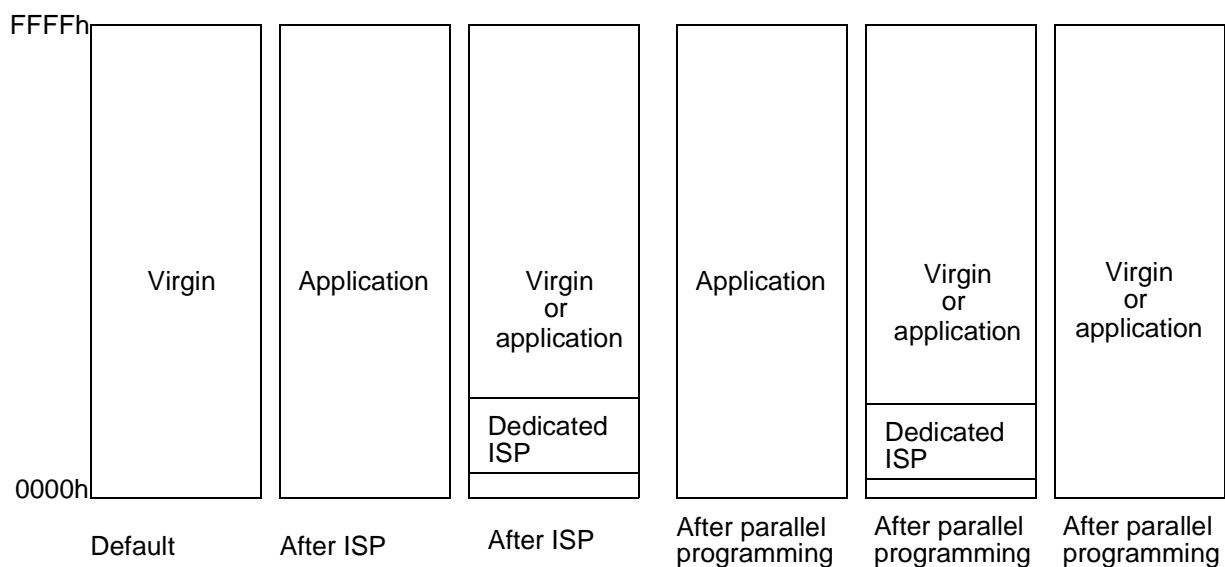

Memory Organization

When the $\overline{EA}$ pin high, the processor fetches instructions from internal program Flash. . If the $\overline{EA}$ pin is tied low, all program memory fetches are from external memory.

Bootloader Architecture

Introduction

The bootloader manages a communication according to a specific defined protocol to provide the whole access and service on Flash memory. Furthermore, all accesses and routines can be called from the user application.

Figure 47. Diagram Context Description

access via specific protocol → Bootloader → Flash memory

access from user application
Acronyms

ISP : In-System Programming

SBV: Software Boot Vector

BSB: Boot Status Byte

SSB: Software Security Bit

HW : Hardware Byte

Functional Description

Figure 48. Bootloader Functional Description
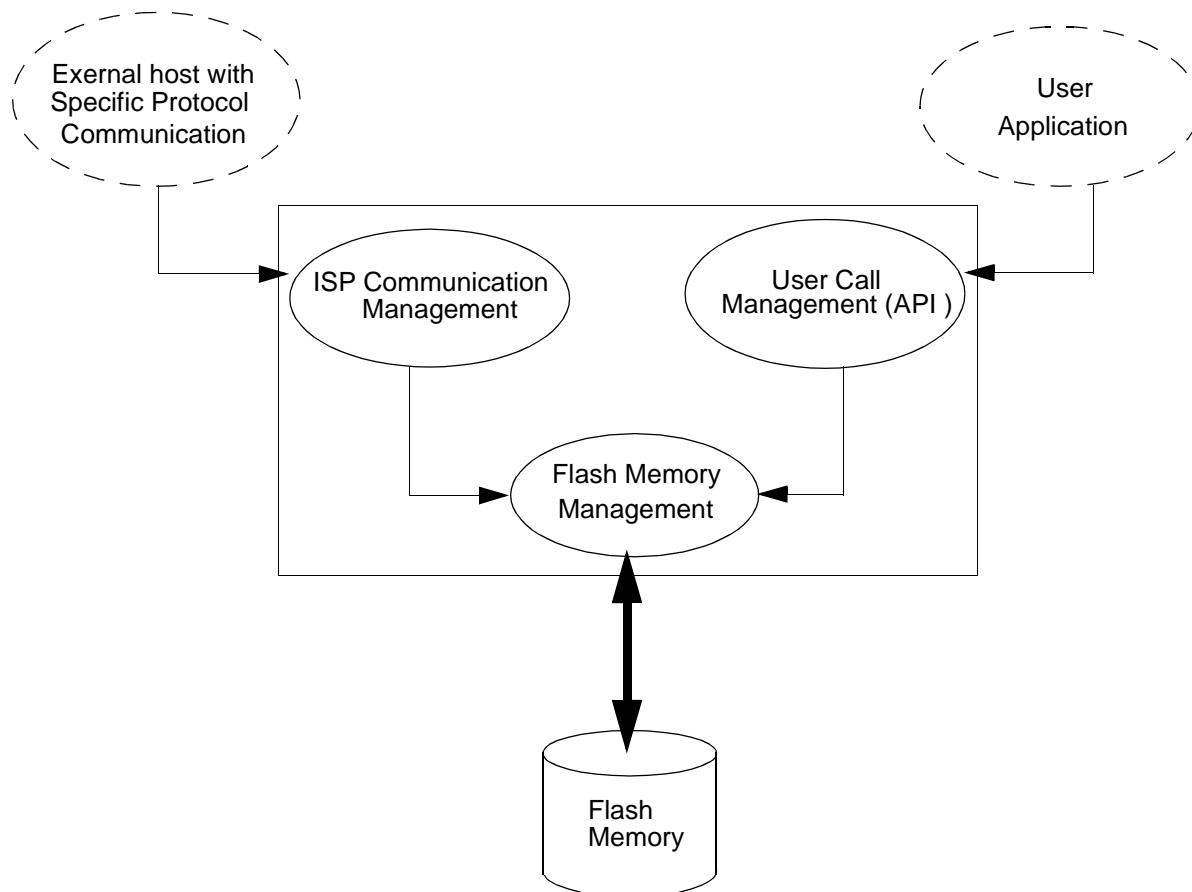

On the above diagram, the on chip bootloader processes are:

• ISP Communication Management

The purpose of this process is to manage the communication and its protocol between the on-chip bootloader and a external device. The on-chip ROM implement a serial protocol (see section Bootloader Protocol). This process translate serial communication frame (UART) into flash memory acess (read, write, erase ...).

• User Call Management

Several Application Program Interface (API) calls are available for use by an application program to permit selective erasing and programming of Flash pages. All calls are made through a common interface (API calls), included in the ROM bootloader. The programming functions are selected by setting up the microcontroller's registers before making a call to a common entry point (0xFFF0). Results are returned in the registers. The purpose on this process is to translate the registers values into internal Flash Memory Management.

• Flash Memory Management

This process manages low level access to flash memory (performs read and write access).

Bootloader Functionality

Introduction

The bootloader can be activated by two means: Hardware conditions or regular boot process.

The Hardware conditions (EA = 1, PSEN = 0) during the Reset# falling edge force the on-chip bootloader execution. This allows an application to be built that will normally execute the end user's code but can be manually forced into default ISP operation.

As PSEN is a an output port in normal operating mode after reset, user application should take care to release PSEN after falling edge of reset signal. The hardware conditions are sampled at reset signal falling edge, thus they can be released at any time when reset input is low.

The on-chip bootloader boot process is shown Figure 49

	Purpose
Hardware Conditions	**The Hardware Conditions force the bootloader execution whatever BLJB, BSB and SBV values.**
BLJB	**The Boot Loader Jump Bit forces the application execution.** **BLJB = 0 => Boot loader execution.** **BLJB = 1 => Application execution** **The BLJB is a fuse bit in the Hardware Byte.** **That can be modified by hardware (programmer) or by software (API).** **Note:** **The BLJB test is perform by hardware to prevent any program execution..**
SBV	**The Software Boot Vector contains the high address of custumer bootloader stored in the application.** **SBV = FCh (default value) if no custumer bootloader in user Flash.** **Note:** **The costumer bootloader is called by JMP [SBV]00h instruction.**

Boot Process

Figure 49. Bootloader Process
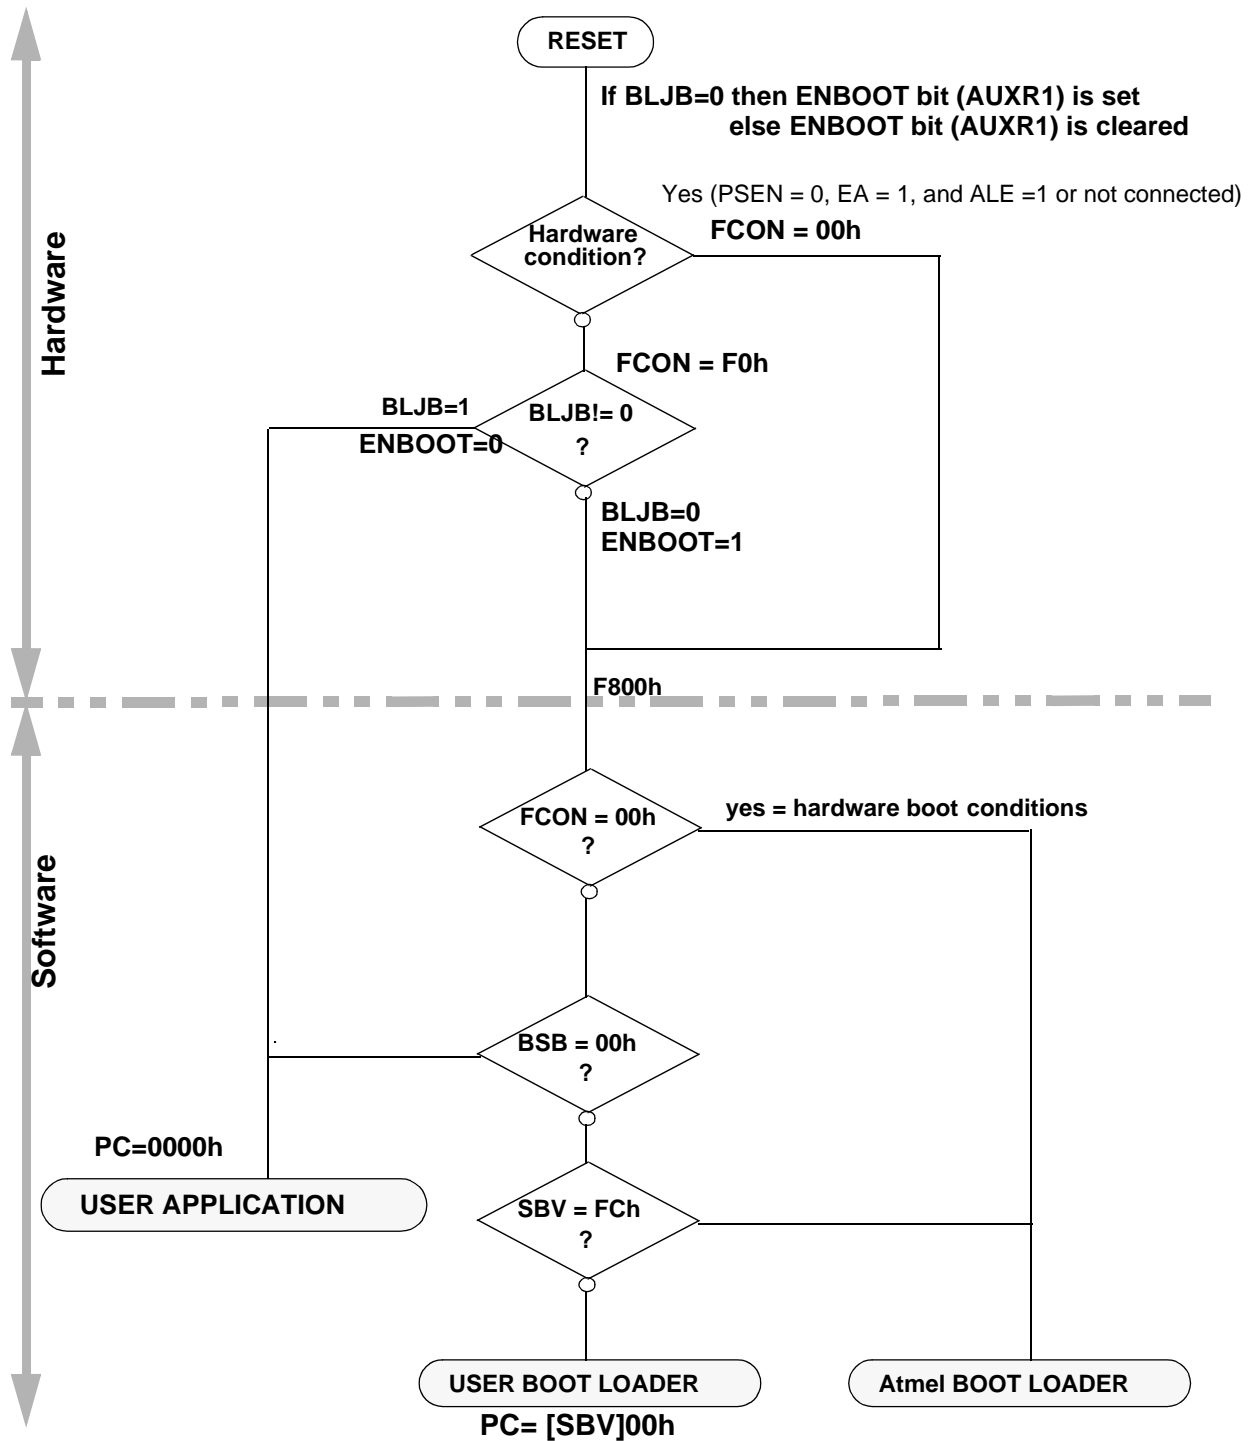

ISP Protocol Description

Physical Layer

The UART used to transmit information has the following configuration:

- Character: 8-bit data
- Parity: none
- Stop: 2 bits
- Flow control: none
- Baudrate: autobaud is performed by the bootloader to compute the baudrate choosen by the host.

Frame Description

The Serial Protocol is based on the Intel Hex-type records.

Intel Hex records consist of ASCII characters used to represent hexadecimal values and are summarized below

Figure 50. Intel Hex Type Frame

Record Mark ':'	Reclen	Load Offset	Record Type	Data or Info	Checksum
1-byte	1-byte	2-bytes	1-byte	n-bytes	1-byte

- Record Mark:

Record Mark is the start of frame. This field must contain ':'.

- Reclen:

Reclen specifies the number of bytes of information or data which follows the Record Type field of the record.

- Load Offset:

Load Offset specifies the 16-bit starting load offset of the data bytes, therefore this field is used only for

Data Program Record (see Section "ISP Commands Summary").

- Record Type:

Record Type specifies the command type. This field is used to interpret the remaining information within the frame. The encoding for all the current record types is described in Section "ISP Commands Summary".

- Data/Info:

Data/Info is a variable length field. It consists of zero or more bytes encoded as pairs of hexadecimal digits. The meaning of data depends on the **Record Type**.

- Checksum:

The two's complement of the 8-bit bytes that result from converting each pair of ASCII hexadecimal digits to one byte of binary, and including the **Reclen** field to and including the last byte of the **Data/Info** field. Therefore, the sum of all the ASCII pairs in a record after converting to binary, from the **Reclen** field to and including the **Checksum** field, is zero.

Functional Description

Software Security Bits (SSB) The SSB protects any Flash access from ISP command.
The command "Program Software Security bit" can only write a higher priority level.

There are three levels of security:

- level 0: **NO_SECURITY** (FFh)

This is the default level.
From level 0, one can write level 1 or level 2.

- level 1: **WRITE_SECURITY** (FEh)

For this level it is impossible to write in the Flash memory, BSB and SBV.
The Bootloader returns 'P' on write access.
From level 1, one can write only level 2.

- level 2: **RD_WR_SECURITY** (FCh

The level 2 forbids all read and write accesses to/from the Flash/EEPROM memory.
The Bootloader returns 'L' on read or write access.
Only a full chip erase in parallel mode (using a programmer) or ISP command can reset
the software security bits.
From level 2, one cannot read and write anything.

Table 93. Software Security Byte Behavior

	Level 0	**Level 1**	**Level 2**
Flash/EEprom	Any access allowed	Read only access allowed	Any access not allowed
Fuse bit	Any access allowed	Read only access allowed	Any access not allowed
BSB & SBV	Any access allowed	Read only access allowed	Any access not allowed
SSB	Any access allowed	Write level 2 allowed	Read only access allowed
Manufacturer info	Read only access allowed	Read only access allowed	Read only access allowed
Bootloader info	Read only access allowed	Read only access allowed	Read only access allowed
Erase block	Allowed	Not allowed	Not allowed
Full chip erase	Allowed	Allowed	Allowed
Blank Check	Allowed	Allowed	Allowed

Full Chip Erase

The ISP command "Full Chip Erase" erases all User Flash memory (fills with FFh) and sets some bytes used by the bootloader at their default values:

- BSB = FFh
- SBV = FCh
- SSB = FFh and finally erase the Software Security Bits

The Full Chip Erase does not affect the bootloader.

Checksum Error

When a checksum error is detected send 'X' followed with CR&LF.

Flow Description

Overview

An initialization step must be performed after each Reset. After microcontroller reset, the bootloader waits for an autobaud sequence (see section 'autobaud performance').

When the communication is initialized the protocol depends on the record type requested by the host.

FLIP, a software utility to implement ISP programming with a PC, is available from the Atmel the web site.

Communication Initialization

The host initializes the communication by sending a 'U' character to help the bootloader to compute the baudrate (autobaud).

Figure 51. Initialization

Table 94. Autobaud Performances

Frequency (MHz) Baudrate (kHz)	1.8432	2	2.4576	3	3.6864	4	5	6	7.3728

Autobaud Performances

The ISP feature allows a wide range of baud rates in the user application. It is also adaptable to a wide range of oscillator frequencies. This is accomplished by measuring the bit-time of a single bit in a received character. This information is then used to program the baud rate in terms of timer counts based on the oscillator frequency. The ISP feature requires that an initial character (an uppercase U) be sent to the AT89C51ID2 to establish the baud rate. Table show the autobaud capability.

Table 94. Autobaud Performances (Continued)

Command Data Stream Protocol

All commands are sent using the same flow. Each frame sent by the host is echoed by the bootloader.

Figure 52. Command Flow
Write / Program Commands   This flow is common to the following frames:

- Flash / Eeprom Programming Data Frame
- EOF or Atmel Frame (only Programming Atmel Frame)
- Config Byte Programming Data Frame
- Baud Rate Frame

Description

Figure 53. Write/Program Flow
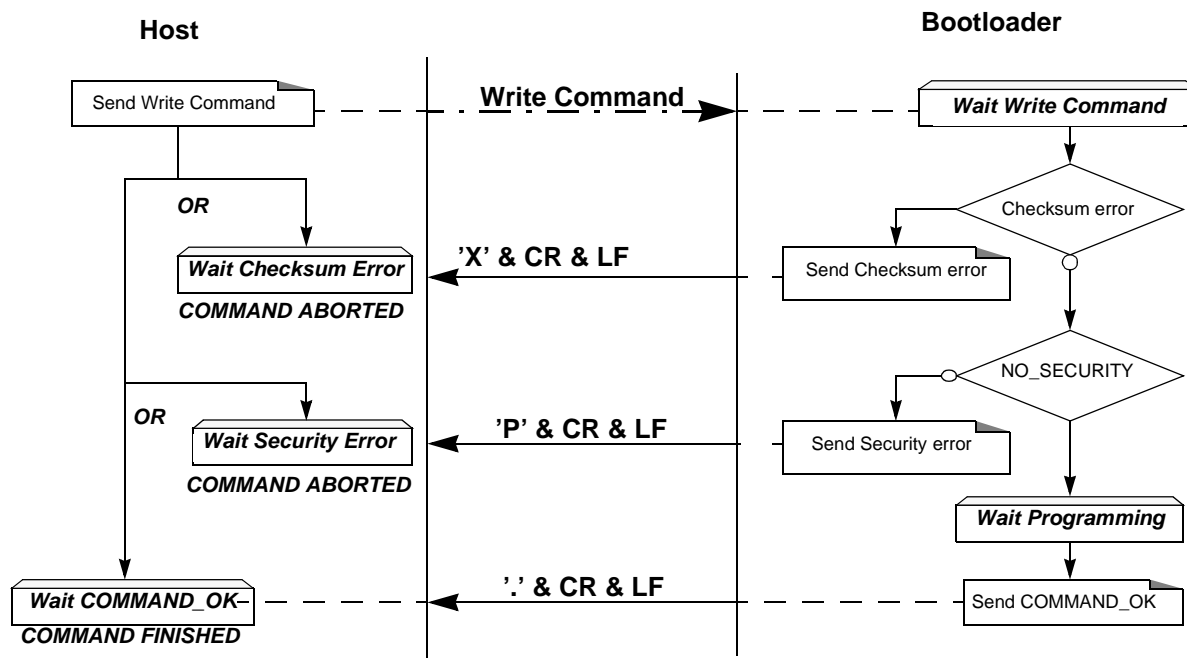

Example

Programming Data (write 55h at address 0010h in the Flash)

HOST	: 01 0010 00 55 9A
BOOTLOADER	: 01 0010 00 55 9A . CR LF

Programming Atmel function (write SSB to level 2)

HOST	: 02 0000 03 05 01 F5
BOOTLOADER	: 02 0000 03 05 01 F5. CR LF

Writing Frame (write BSB to 55h)

HOST	: 03 0000 03 06 00 55 9F
BOOTLOADER	: 03 0000 03 06 00 55 9F . CR LF

131

Blank Check Command

Description

Figure 54. Blank Check Flow

Example

Blank Check ok

HOST	: 05 0000 04 0000 7FFF 01 78
BOOTLOADER	: 05 0000 04 0000 7FFF 01 78 . CR LF

Blank Check ko at address xxxx

HOST	: 05 0000 04 0000 7FFF 01 78
BOOTLOADER	: 05 0000 04 0000 7FFF 01 78 xxxx CR LF

Blank Check with checksum error

HOST	: 05 0000 04 0000 7FFF 01 70
BOOTLOADER	: 05 0000 04 0000 7FFF 01 70 X CR LF CR LF

Display Data

Description

Figure 55. Display Flow
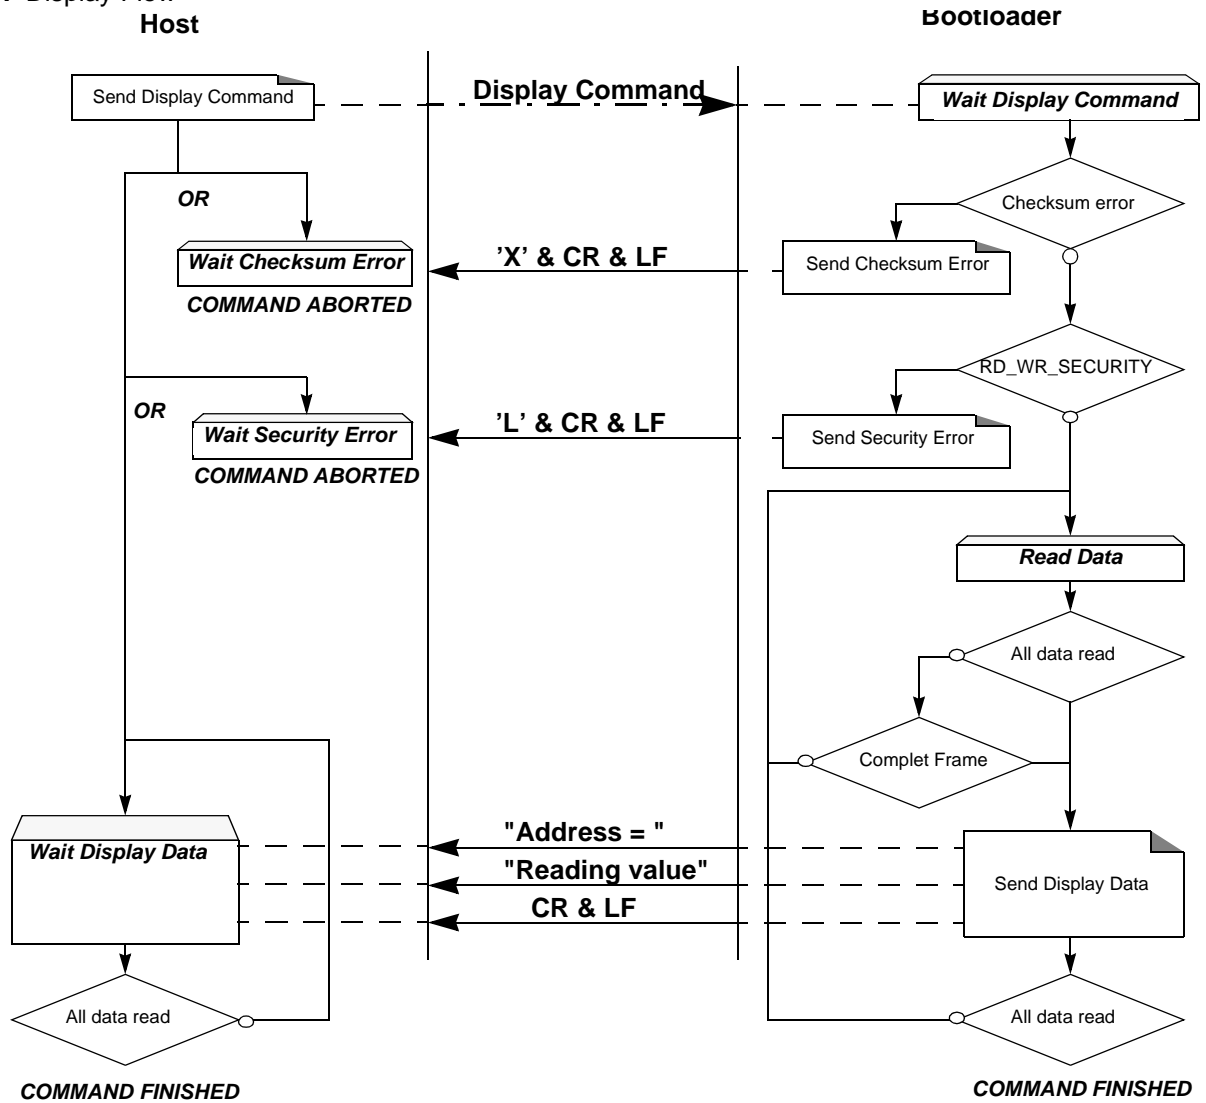

Note: The maximum size of block is 400h. To read more than 400h bytes, the Host must send a new command.

<u>Display data from address 0000h to 0020h</u>

```
HOST             : 05 0000 04 0000 0020 00 D7
BOOTLOADER       : 05 0000 04 0000 0020 00 D7
BOOTLOADER       0000=-----data------ CR LF   (16 data)
BOOTLOADER       0010=-----data------ CR LF   (16 data)
BOOTLOADER       0020=data CR LF              ( 1 data)
```

Read Function   This flow is similar for the following frames:

- Reading Frame
- EOF Frame/ Atmel Frame (only reading Atmel Frame)

Description

Figure 56. Read Flow
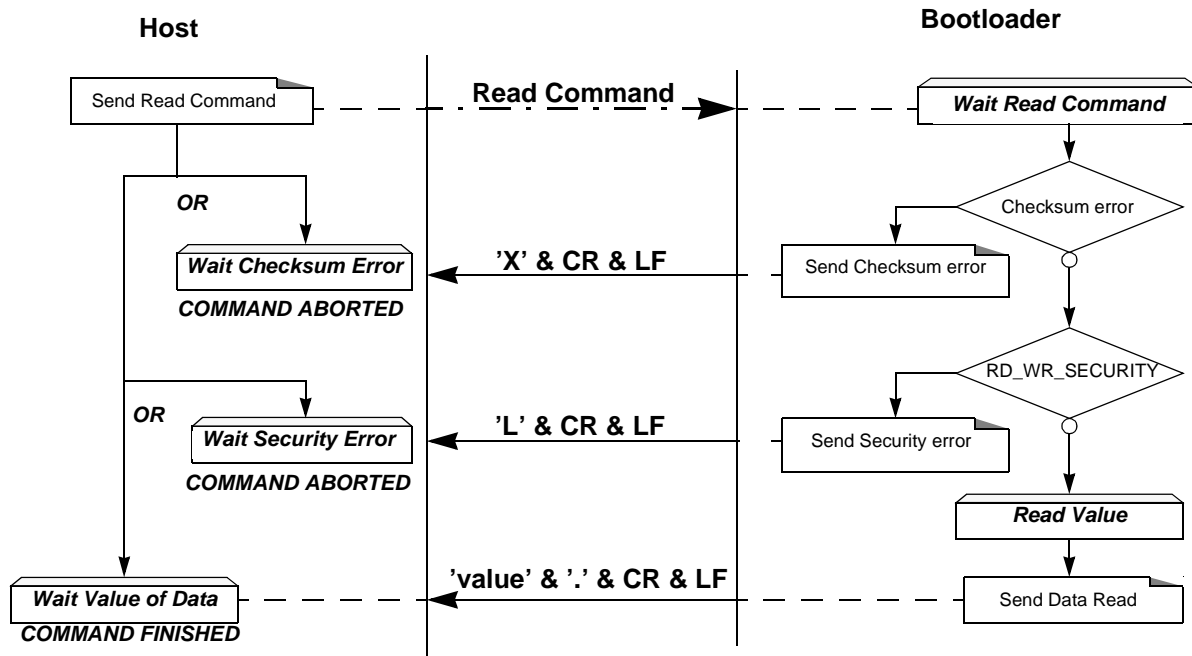

Example

Read function (read SBV)

| **HOST** | : 02 0000 05 07 02 F0 |
| **BOOTLOADER** | : 02 0000 05 07 02 F0 Value . CR LF |

Atmel Read function (read Bootloader version)

| **HOST** | : 02 0000 01 02 00 FB |
| **BOOTLOADER** | : 02 0000 01 02 00 FB Value . CR LF |

Table 95. ISP Commands Summary

Command	Command Name	data[0]	data[1]	Command Effect
00h	Program Data			Program Nb Data Byte. Bootloader will accept up to 128 (80h) data bytes. The data bytes should be 128 byte page flash boundary.
03h	Write Function	01h	00h	Erase block0 (0000h-1FFFh)
			20h	Erase block1 (2000h-3FFFh)
			40h	Erase block2 (4000h-7FFFh)
			80h	Erase block3 (8000h- BFFFh)
			C0h	Erase block4 (C000h- FFFFh)
		03h	00h	Hardware Reset
			01h	Ljmp Address (data[2:3]= Address)
		04h	00h	Erase SBV & BSB
		05h	00h	Program SSB level 1
			01h	Program SSB level 2
		06h	00h	Program BSB (value to write in data[2])
			01h	Program SBV (value to write in data[2])
		07h	-	Full Chip Erase
		0Ah	02h	Program Osc fuse (value to write in data[2])
			04h	Program BLJB fuse (value to write in data[2])
			08h	Program X2 fuse (value to write in data[2])
04h	Display Function	Data[0:1] = start address Data [2:3] = end address Data[4] = 00h -> Display data Data[4] = 01h -> Blank check		Display Data
				Blank Check

Table 95. ISP Commands Summary (Continued)

Command	Command Name	data[0]	data[1]	Command Effect
05h	Read Function	00h	00h	Manufacturer Id
			01h	Device Id #1
			02h	Device Id #2
			03h	Device Id #3
		07h	00h	Read SSB
			01h	Read BSB
			02h	Read SBV
			06h	Read Extra Byte
		0Bh	00h	Read Hardware Byte
		0Eh	00h	Read Device Boot ID1
			01h	Read Device Boot ID2
		0Fh	00h	Read Bootloader Version

API Call Description

Several Application Program Interface (API) calls are available for use by an application program to permit selective erasing and programming of Flash pages. All calls are made through a common interface, PGM_MTP. The programming functions are selected by setting up the microcontroller's registers before making a call to PGM_MTP at FFF0h. Results are returned in the registers.

When several bytes have to be programmed, it is highly recommended to use the Atmel API "PROGRAM DATA PAGE" call. Indeed, this API call writes up to 128 bytes in a single command.

All routines for software access are provided in the C Flash driver available on Atmel web site.

The API calls description and arguments are shown in Table

Table 96. API Call Summary

Command	R1	A	DPTR0	DPTR1	Returned Value	Command Effect
READ MANUF ID	00h	XXh	0000h	XXh	ACC=Manufacturer Id	Read Manufacturer identifier
READ DEVICE ID1	00h	XXh	0001h	XXh	ACC= Device Id 1	Read Device identifier 1
READ DEVICE ID2	00h	XXh	0002h	XXh	ACC=Device Id 2	Read Device identifier 2
READ DEVICE ID3	00h	XXh	0003h	XXh	ACC=Device Id 3	Read Device identifier 3
ERASE BLOCK	01h	XXh	DPH=00h	00h	ACC=DPH	Erase block 0
			DPH=20h			Erase block 1
			DPH=40h			Erase block 2
			DPH=80h			Erase block 3
			DPH=C0h			Erase block 4
PROGRAM DATA BYTE	02h	Byte value to program	Address of byte to program		ACC=0 : DONE	Program one Data Byte in user flash
ERASE BOOT VECTOR	04h	XXh	XXh	XXh	ACC=FCh	Erase Software boot vector and boot status byte. (SBV=FCh and BSB=FFh)
PROGRAM SSB	05h	XXh	DPH=00h DPL=00h	00h	ACC= SSB value	Set SSB level 1
			DPH=00h DPL=01h			Set SSB level 2
			DPH=00h DPL=10h			Set SSB level 0
			DPH=00h DPL=11h			Set SSB level 1
PROGRAM BSB	06h	New BSB value	0000h	XXh	none	Program boot status byte
PROGRAM SBV	06h	New SBV value	0001h	XXh	none	Program software boot vector
READ SSB	07h	XXh	0000h	XXh	ACC=SSB	Read Software Security Byte
READ HSB	07h	XXh	0004h	XXh	ACC=HSB	Read Hardware Byte
READ BSB	07h	XXh	0001h	XXh	ACC=BSB	Read Boot Status Byte
READ SBV	07h	XXh	0002h	XXh	ACC=SBV	Read Software Boot Vector

Table 96. API Call Summary (Continued)

Command	R1	A	DPTR0	DPTR1	Returned Value	Command Effect
READ MANUF ID	00h	XXh	0000h	XXh	ACC=Manufacturer Id	Read Manufacturer identifier
READ DEVICE ID1	00h	XXh	0001h	XXh	ACC= Device Id 1	Read Device identifier 1
READ DEVICE ID2	00h	XXh	0002h	XXh	ACC=Device Id 2	Read Device identifier 2
READ DEVICE ID3	00h	XXh	0003h	XXh	ACC=Device Id 3	Read Device identifier 3
ERASE BLOCK	01h	XXh	DPH=00h	00h	ACC=DPH	Erase block 0
			DPH=20h			Erase block 1
			DPH=40h			Erase block 2
			DPH=80h			Erase block 3
			DPH=C0h			Erase block 4
PROGRAM DATA PAGE	09h	Number of byte to program	Address of the first byte to program in the Flash memory	Address in XRAM of the first data to program	ACC=0 : DONE	Program up to 128 bytes in user flash. Remark: number of bytes to program is limited such as the Flash write remains in a single 128bytes page. Hence, when ACC is 128, valid values of DPL are 00h, or, 80h.
PROGRAM X2 FUSE	0Ah	Fuse value 00h or 01h	0008h	XXh	none	Program X2 fuse bit with ACC
PROGRAM BLJB FUSE	0Ah	Fuse value 00h or 01h	0004h	XXh	none	Program BLJB fuse bit with ACC
READ BOOT ID1	0Eh	XXh	DPL=00h	XXh	ACC=ID1	Read boot ID1
READ BOOT ID2	0Eh	XXh	DPL=01h	XXh	ACC=ID2	Read boot ID2
READ BOOT VERSION	0Fh	XXh	XXXXh	XXh	ACC=Boot_Version	Read bootloader version

Electrical Characteristics

Absolute Maximum Ratings

I = industrial ....-40°C to 85°C
Storage Temperature .... -65°C to + 150°C
Voltage on V_{CC} to V_{SS} (standard voltage) ....-0.5V to + 6.5V
Voltage on V_{CC} to V_{SS} (low voltage)..................-0.5V to + 4.5V
Voltage on Any Pin to V_{SS}.........................-0.5V to V_{CC} + 0.5V
Power Dissipation .... 1 W[2]

Note: Stresses at or above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions may affect device reliability.
Power dissipation is based on the maximum allowable die temperature and the thermal resistance of the package.

DC Parameters

T_A = -40°C to +85°C; V_{SS} = 0V; V_{CC} =2.7V to 5.5V; F = 0 to 60 MHz

Symbol	Parameter	Min	Typ	Max	Unit	Test Conditions
V_{IL}	Input Low Voltage	-0.5		0.2 V_{CC} - 0.1	V	
V_{IH}	Input High Voltage except RST, XTAL1	0.2 V_{CC} + 0.9		V_{CC} + 0.5	V	
V_{IH1}	Input High Voltage RST, XTAL1	0.7 V_{CC}		V_{CC} + 0.5	V	
V_{OL}	Output Low Voltage, ports 1, 2, 3, 4 [6]			0.3 0.45 1.0	V V V	V_{CC} = 4.5V to 5.5V I_{OL} = 100 μA[4] I_{OL} = 1.6 mA[4] I_{OL} = 3.5 mA[4]
				0.45	V	V_{CC} = 2.7V to 5.5V I_{OL} = 0.8 mA[4]
V_{OL1}	Output Low Voltage, port 0, ALE, $\overline{PSEN}$ [6]			0.3 0.45 1.0	V V V	V_{CC} = 4.5V to 5.5V I_{OL} = 200 μA[4] I_{OL} = 3.2 mA[4] I_{OL} = 7.0 mA[4]
				0.45	V	V_{CC} = 2.7V to 5.5V I_{OL} = 1.6 mA[4]
V_{OH}	Output High Voltage, ports 1, 2, 3, 4	V_{CC} - 0.3 V_{CC} - 0.7 V_{CC} - 1.5			V V V	V_{CC} = 5V ± 10% I_{OH} = -10 μA I_{OH} = -30 μA I_{OH} = -60 μA
		0.9 V_{CC}			V	V_{CC} = 2.7V to 5.5V I_{OH} = -10 μA
V_{OH1}	Output High Voltage, port 0, ALE, $\overline{PSEN}$	V_{CC} - 0.3 V_{CC} - 0.7 V_{CC} - 1.5			V V V	V_{CC} = 5V ± 10% I_{OH} = -200 μA I_{OH} = -3.2 mA I_{OH} = -7.0 mA
		0.9 V_{CC}			V	V_{CC} = 2.7V to 5.5V I_{OH} = -10 μA

T_A = -40°C to +85°C; V_{SS} = 0V; V_{CC} =2.7V to 5.5V; F = 0 to 60 MHz (Continued)

Symbol	Parameter	Min	Typ	Max	Unit	Test Conditions
R_{RST}	RST Pull-down Resistor	50	200[5]	250	kΩ	
I_{IL}	Logical 0 Input Current ports 1, 2, 3, 4 and 5			-50	μA	V_{IN} = 0.45V
I_{LI}	Input Leakage Current			±10	μA	0.45V < V_{IN} < V_{CC}
I_{TL}	Logical 1 to 0 Transition Current, ports 1, 2, 3, 4			-650	μA	V_{IN} = 2.0V
C_{IO}	Capacitance of I/O Buffer			10	pF	F_C = 3 MHz T_A = 25°C
I_{PD}	Power-down Current		75	150	μA	2.7 < V_{CC} < 5.5V[3]
I_{CCOP}	Power Supply Current on normal mode			0.4 x Frequency (MHz) + 5	mA	V_{CC} = 5.5V[1]
I_{CCIDLE}	Power Supply Current on idle mode			0.3 x Frequency (MHz) + 5	mA	V_{CC} = 5.5V[2]
$I_{CCWRITE}$	Power Supply Current on flash or EEdata write			0.8 x Frequency (MHz) + 15	mA	V_{CC} = 5.5V
t_{WRITE}	Flash or EEdata programming time		7	10	ms	2.7 < V_{CC} < 5.5V

Notes: 1. Operating I_{CC} is measured with all output pins disconnected; XTAL1 driven with T_{CLCH}, T_{CHCL} = 5 ns (see Figure 60), V_{IL} = V_{SS} + 0.5V, V_{IH} = V_{CC} - 0.5V; XTAL2 N.C.; $\overline{EA}$ = RST = Port 0 = V_{CC}. I_{CC} would be slightly higher if a crystal oscillator used (see Figure 57).

2. Idle I_{CC} is measured with all output pins disconnected; XTAL1 driven with T_{CLCH}, T_{CHCL} = 5 ns, V_{IL} = V_{SS} + 0.5V, V_{IH} = V_{CC} - 0.5V; XTAL2 N.C; Port 0 = V_{CC}; $\overline{EA}$ = RST = V_{SS} (see Figure 58).

3. Power-down I_{CC} is measured with all output pins disconnected; $\overline{EA}$ = V_{CC}, PORT 0 = V_{CC}; XTAL2 NC.; RST = V_{SS} (see Figure 59).

4. Capacitance loading on Ports 0 and 2 may cause spurious noise pulses to be superimposed on the V_{OLS} of ALE and Ports 1 and 3. The noise is due to external bus capacitance discharging into the Port 0 and Port 2 pins when these pins make 1 to 0 transitions during bus operation. In the worst cases (capacitive loading 100 pF), the noise pulse on the ALE line may exceed 0.45V with maxi V_{OL} peak 0.6V. A Schmitt Trigger use is not necessary.

5. Typical values are based on a limited number of samples and are not guaranteed. The values listed are at room temperature and 5V.

6. Under steady state (non-transient) conditions, I_{OL} must be externally limited as follows:
Maximum I_{OL} per port pin: 10 mA
Maximum I_{OL} per 8-bit port:
Port 0: 26 mA
Ports 1, 2 and 3: 15 mA
Maximum total I_{OL} for all output pins: 71 mA
If I_{OL} exceeds the test condition, V_{OL} may exceed the related specification. Pins are not guaranteed to sink current greater than the listed test conditions.

Figure 57. I_{CC} Test Condition, Active Mode
All other pins are disconnected.

Figure 58. I_{CC} Test Condition, Idle Mode
All other pins are disconnected.

Figure 59. I_{CC} Test Condition, Power-down Mode
All other pins are disconnected.

Figure 60. Clock Signal Waveform for I_{CC} Tests in Active and Idle Modes
AC Parameters

Explanation of the AC Symbols

Each timing symbol has 5 characters. The first character is always a "T" (stands for time). The other characters, depending on their positions, stand for the name of a signal or the logical status of that signal. The following is a list of all the characters and what they stand for.

Example: T_{AVLL} = Time for Address Valid to ALE Low.
T_{LLPL} = Time for ALE Low to PSEN Low.

(Load Capacitance for port 0, ALE and PSEN = 100 pF; Load Capacitance for all other outputs = 80 pF.)

Table 97 Table 100, and Table 103 give the description of each AC symbols.

Table 98, Table 99, Table 101 and Table 104 gives the range for each AC parameter.

Table 98, Table 99 and Table 105 give the frequency derating formula of the AC parameter for each speed range description. To calculate each AC symbols. take the x value in the correponding column (-M or -L) and use this value in the formula.

Example: T_{LLIU} for -M and 20 MHz, Standard clock.
x = 35 ns
T 50 ns
$T_{CCIV} = 4T - x = 165$ ns

External Program Memory Characteristics

Table 97. Symbol Description

| Symbol	Parameter
T	Oscillator clock period
T_{LHLL}	ALE pulse width
T_{AVLL}	Address Valid to ALE

T_{XHDX}	Min	x	x	0	0	ns
T_{XHDV}	Max	10 T - x	5 T- x	133	133	ns

Shift Register Timing Waveforms
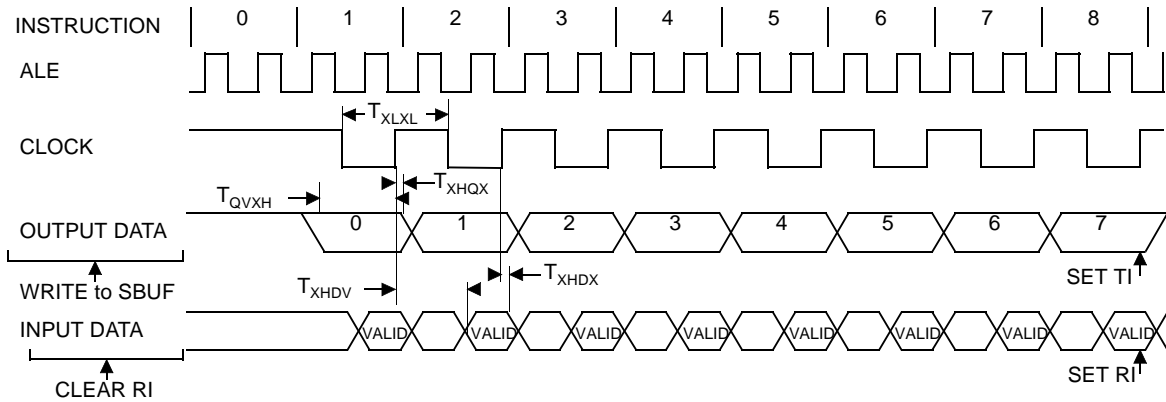

External Clock Drive Waveforms
**AC Testing Input/Output
Waveforms**

INPUT/OUTPUT

V_{CC} -0.5V ⟍ ⟋ 0.2 V_{CC} + 0.9 ⟍ ⟋

0.45V ⟋ ⟍ 0.2 V_{CC} - 0.1 ⟋
AC inputs during testing are driven at V_{CC} - 0.5 for a logic "1" and 0.45V for a logic "0".
Timing measurement are made at V_{IH} min for a logic "1" and V_{IL} max for a logic "0".

Float Waveforms

◄————— FLOAT —————►

V_{OH} - 0.1V V_{LOAD} V_{LOAD} + 0.1V

V_{OL} + 0.1V V_{LOAD} - 0.1V
For timing purposes as port pin is no longer floating when a 100 mV change from load
voltage occurs and begins to float when a 100 mV change from the loaded V_{OH}/V_{OL} level
occurs. $I_{OL}/I_{OH} \geq \pm$ 20 mA.

Clock Waveforms   Valid in normal clock mode. In X2 mode XTAL2 must be changed to XTAL2/2.

149

Figure 61. Internal Clock Signals
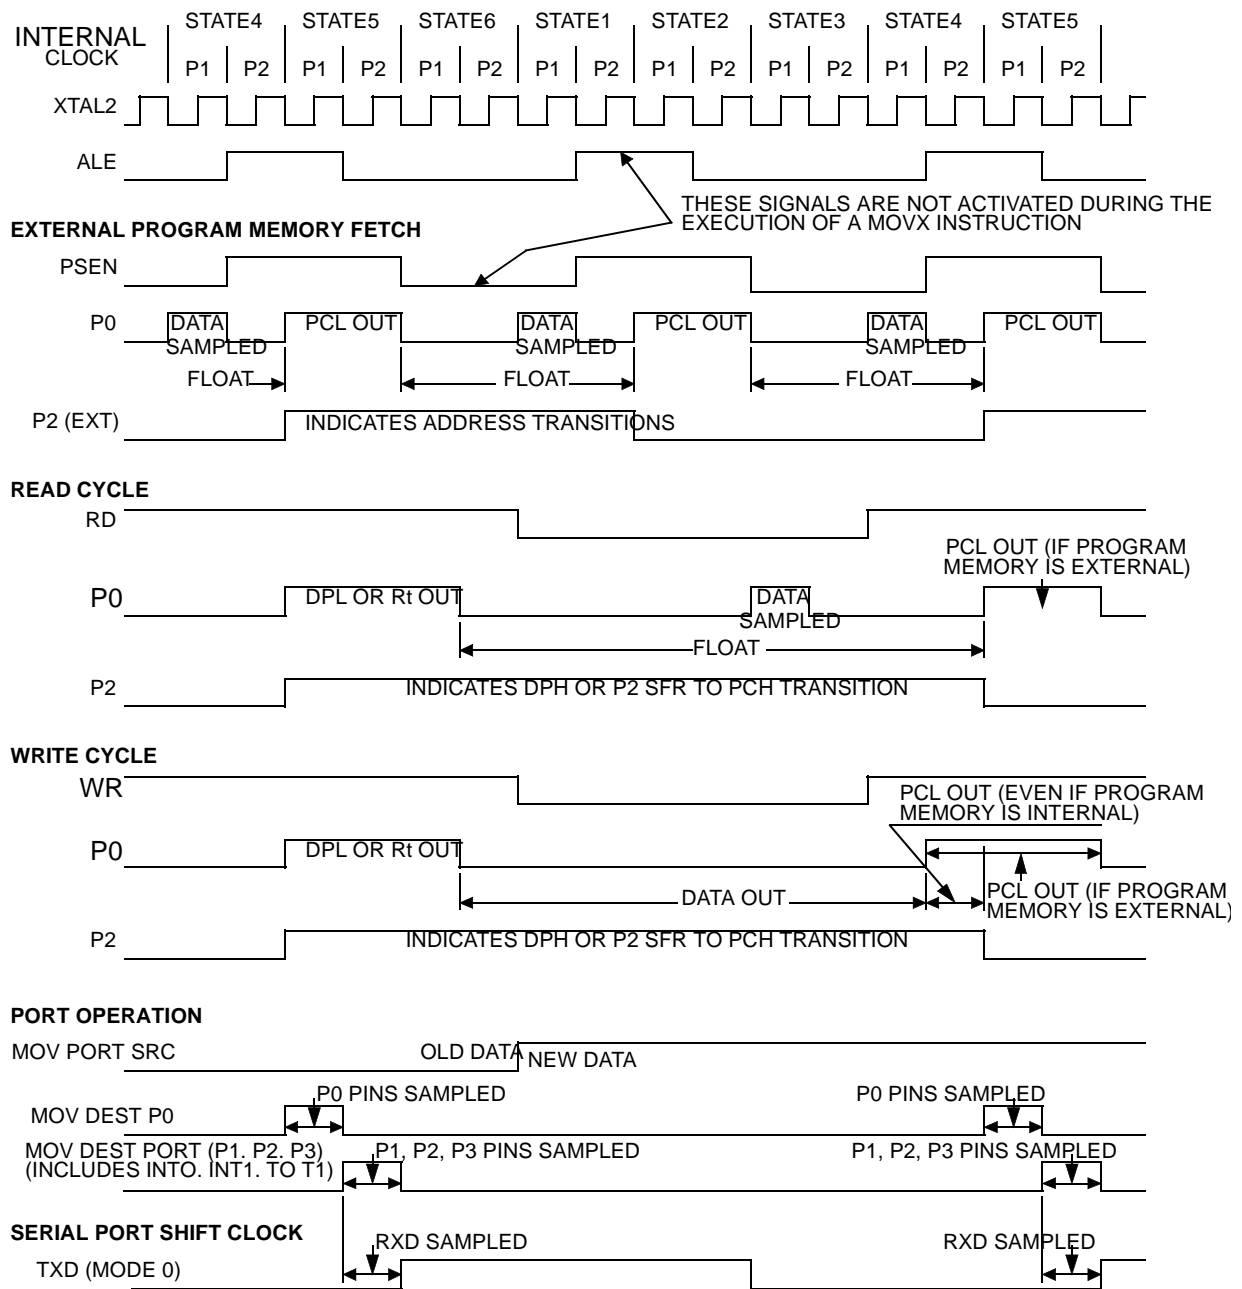

This diagram indicates when signals are clocked internally. The time it takes the signals to propagate to the pins, however, ranges from 25 to 125 ns. This propagation delay is dependent on variables such as temperature and pin loading. Propagation also varies from output to output and component. Typically though ($T_A = 25°C$ fully loaded) RD and $\overline{WR}$ propagation delays are approximately 50 ns. The other signals are typically 85 ns. Propagation delays are incorporated in the AC specifications.

Ordering Information

Table 106. Possible Order Entries

Part Number	Supply Voltage	Temperature Range	Package	Packing
AT89C51ID2-SLSIM			PLCC44	Stick
AT89C51ID2-RLTIM	2.7V-5.5V	Industrial	VQFP44	Tray
AT89C51ID2-SMSIM[1]			PLCC68	Stick
AT89C51ID2-RDTIM[1]			VQFP64	Tray

Note: 1. For PLCC68 and VQFP64 packages, please contact Atmel sales office for availability.
